The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_Low on page 17-475
The MAC Address41 Low register holds the lower 32 bits of the 42th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address42_High on page 17-476
The MAC Address42 High register holds the upper 16 bits of the 43th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address42 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address42_Low on page 17-479
The MAC Address42 Low register holds the lower 32 bits of the 43th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address43_High on page 17-480
The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_Low on page 17-483
The MAC Address43 Low register holds the lower 32 bits of the 44th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address44_High on page 17-484
The MAC Address44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address44 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address44_Low on page 17-487
The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address45_High on page 17-488
The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_Low on page 17-491
The MAC Address45 Low register holds the lower 32 bits of the 46th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address46_High on page 17-492
The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address46_Low on page 17-495
The MAC Address46 Low register holds the lower 32 bits of the 47th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address47_High on page 17-496
The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_Low on page 17-499
The MAC Address47 Low register holds the lower 32 bits of the 48th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address48_High on page 17-500
The MAC Address48 High register holds the upper 16 bits of the 49th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address48 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address48_Low on page 17-503
The MAC Address48 Low register holds the lower 32 bits of the 49th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address49_High on page 17-504
The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_Low on page 17-507
The MAC Address49 Low register holds the lower 32 bits of the 50th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address50_High on page 17-508
The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address50_Low on page 17-511
The MAC Address50 Low register holds the lower 32 bits of the 51th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address51_High on page 17-512
The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_Low on page 17-515
The MAC Address51 Low register holds the lower 32 bits of the 52th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address52_High on page 17-516
The MAC Address52 High register holds the upper 16 bits of the 53th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address52 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address52_Low on page 17-519
The MAC Address52 Low register holds the lower 32 bits of the 53th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address53_High on page 17-520
The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_Low on page 17-523
The MAC Address53 Low register holds the lower 32 bits of the 54th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address54_High on page 17-524
The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_Low on page 17-527
The MAC Address54 Low register holds the lower 32 bits of the 55th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address55_High on page 17-528
The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_Low on page 17-531
The MAC Address55 Low register holds the lower 32 bits of the 56th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address56_High on page 17-532
The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address56_Low on page 17-535
The MAC Address56 Low register holds the lower 32 bits of the 57th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address57_High on page 17-536
The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_Low on page 17-539
The MAC Address57 Low register holds the lower 32 bits of the 58th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address58_High on page 17-540
The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address58_Low on page 17-543
The MAC Address58 Low register holds the lower 32 bits of the 59th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address59_High on page 17-544
The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_Low on page 17-547
The MAC Address59 Low register holds the lower 32 bits of the 60th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address60_High on page 17-548
The MAC Address60 High register holds the upper 16 bits of the 61th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address60 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address60_Low on page 17-551
The MAC Address60 Low register holds the lower 32 bits of the 61th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address61_High on page 17-552
The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_Low on page 17-555
The MAC Address61 Low register holds the lower 32 bits of the 62th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address62_High on page 17-556
The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_Low on page 17-559
The MAC Address62 Low register holds the lower 32 bits of the 63th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address63_High on page 17-560
The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address63_Low on page 17-563
The MAC Address63 Low register holds the lower 32 bits of the 64th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address64_High on page 17-564
The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_Low on page 17-567
The MAC Address64 Low register holds the lower 32 bits of the 65th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address65_High on page 17-568
The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address65_Low on page 17-571
The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address66_High on page 17-572
The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_Low on page 17-575
The MAC Address66 Low register holds the lower 32 bits of the 67th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address67_High on page 17-576
The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_Low on page 17-579
The MAC Address67 Low register holds the lower 32 bits of the 68th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address68_High on page 17-580
The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_Low on page 17-583
The MAC Address68 Low register holds the lower 32 bits of the 69th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address69_High on page 17-584
The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address69_Low on page 17-587
The MAC Address69 Low register holds the lower 32 bits of the 70th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address70_High on page 17-588
The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_Low on page 17-591
The MAC Address70 Low register holds the lower 32 bits of the 71th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address71_High on page 17-592
The MAC Address71 High register holds the upper 16 bits of the 72th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address71 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address71_Low on page 17-595
The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address72_High on page 17-596
The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address72_Low on page 17-599
The MAC Address72 Low register holds the lower 32 bits of the 73th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address73_High on page 17-600
The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address73_Low on page 17-603
The MAC Address73 Low register holds the lower 32 bits of the 74th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address74_High on page 17-604
The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_Low on page 17-607
The MAC Address74 Low register holds the lower 32 bits of the 75th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address75_High on page 17-608
The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_Low on page 17-611
The MAC Address75 Low register holds the lower 32 bits of the 76th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address76_High on page 17-612
The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_Low on page 17-615
The MAC Address76 Low register holds the lower 32 bits of the 77th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address77_High on page 17-616
The MAC Address77 High register holds the upper 16 bits of the 78th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address77 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address77_Low on page 17-619
The MAC Address77 Low register holds the lower 32 bits of the 78th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address78_High on page 17-620
The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address78_Low on page 17-623
The MAC Address78 Low register holds the lower 32 bits of the 79th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address79_High on page 17-624
The MAC Address79 High register holds the upper 16 bits of the 80th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address79 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address79_Low on page 17-627
The MAC Address79 Low register holds the lower 32 bits of the 80th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address80_High on page 17-628
The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_Low on page 17-631
The MAC Address80 Low register holds the lower 32 bits of the 81th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address81_High on page 17-632
The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_Low on page 17-635
The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address82_High on page 17-636
The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address82_Low on page 17-639
The MAC Address82 Low register holds the lower 32 bits of the 83th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address83_High on page 17-640
The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_Low on page 17-643
The MAC Address83 Low register holds the lower 32 bits of the 84th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address84_High on page 17-644
The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_Low on page 17-647
The MAC Address84 Low register holds the lower 32 bits of the 85th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address85_High on page 17-648
The MAC Address85 High register holds the upper 16 bits of the 86th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address85 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address85_Low on page 17-651
The MAC Address85 Low register holds the lower 32 bits of the 86th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address86_High on page 17-652
The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_Low on page 17-655
The MAC Address86 Low register holds the lower 32 bits of the 87th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address87_High on page 17-656
The MAC Address87 High register holds the upper 16 bits of the 88th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address87 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address87_Low on page 17-659
The MAC Address87 Low register holds the lower 32 bits of the 88th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address88_High on page 17-660
The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_Low on page 17-663
The MAC Address88 Low register holds the lower 32 bits of the 89th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address89_High on page 17-664
The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_Low on page 17-667
The MAC Address89 Low register holds the lower 32 bits of the 90th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address90_High on page 17-668
The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_Low on page 17-671
The MAC Address90 Low register holds the lower 32 bits of the 91th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address91_High on page 17-672
The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address91_Low on page 17-675
The MAC Address91 Low register holds the lower 32 bits of the 92th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address92_High on page 17-676
The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address92_Low on page 17-679
The MAC Address92 Low register holds the lower 32 bits of the 93th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address93_High on page 17-680
The MAC Address93 High register holds the upper 16 bits of the 94th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address93 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address93_Low on page 17-683
The MAC Address93 Low register holds the lower 32 bits of the 94th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address94_High on page 17-684
The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_Low on page 17-687
The MAC Address94 Low register holds the lower 32 bits of the 95th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address95_High on page 17-688
The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address95_Low on page 17-691
The MAC Address95 Low register holds the lower 32 bits of the 96th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address96_High on page 17-692
The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_Low on page 17-695
The MAC Address96 Low register holds the lower 32 bits of the 97th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address97_High on page 17-696
The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address97_Low on page 17-699
The MAC Address97 Low register holds the lower 32 bits of the 98th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address98_High on page 17-700
The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_Low on page 17-703
The MAC Address98 Low register holds the lower 32 bits of the 99th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address99_High on page 17-704
The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_Low on page 17-707
The MAC Address99 Low register holds the lower 32 bits of the 100th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address100_High on page 17-708
The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_Low on page 17-711
The MAC Address100 Low register holds the lower 32 bits of the 101th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address101_High on page 17-712
The MAC Address101 High register holds the upper 16 bits of the 102th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address101 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address101_Low on page 17-715
The MAC Address101 Low register holds the lower 32 bits of the 102th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address102_High on page 17-716
The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_Low on page 17-719
The MAC Address102 Low register holds the lower 32 bits of the 103th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address103_High on page 17-720
The MAC Address103 High register holds the upper 16 bits of the 104th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address103_Low on page 17-723
The MAC Address103 Low register holds the lower 32 bits of the 104th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address104_High on page 17-724
The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_Low on page 17-727
The MAC Address104 Low register holds the lower 32 bits of the 105th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address105_High on page 17-728
The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_Low on page 17-731
The MAC Address105 Low register holds the lower 32 bits of the 106th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address106_High on page 17-732
The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address106_Low on page 17-735
The MAC Address106 Low register holds the lower 32 bits of the 107th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address107_High on page 17-736
The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_Low on page 17-739
The MAC Address107 Low register holds the lower 32 bits of the 108th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address108_High on page 17-740
The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_Low on page 17-743
The MAC Address108 Low register holds the lower 32 bits of the 109th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address109_High on page 17-744
The MAC Address109 High register holds the upper 16 bits of the 110th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address109 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address109_Low on page 17-747
The MAC Address109 Low register holds the lower 32 bits of the 110th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address110_High on page 17-748
The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_Low on page 17-751
The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address111_High on page 17-752
The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address111_Low on page 17-755
The MAC Address111 Low register holds the lower 32 bits of the 112th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address112_High on page 17-756
The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address112_Low on page 17-759
The MAC Address112 Low register holds the lower 32 bits of the 113th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address113_High on page 17-760
The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_Low on page 17-763
The MAC Address113 Low register holds the lower 32 bits of the 114th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address114_High on page 17-764
The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_Low on page 17-767
The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address115_High on page 17-768
The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address115_Low on page 17-771
The MAC Address115 Low register holds the lower 32 bits of the 116th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address116_High on page 17-772
The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_Low on page 17-775
The MAC Address116 Low register holds the lower 32 bits of the 117th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address117_High on page 17-776
The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address117_Low on page 17-779
The MAC Address117 Low register holds the lower 32 bits of the 118th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address118_High on page 17-780
The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_Low on page 17-783
The MAC Address118 Low register holds the lower 32 bits of the 119th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address119_High on page 17-784
The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_Low on page 17-787
The MAC Address119 Low register holds the lower 32 bits of the 120th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address120_High on page 17-788
The MAC Address120 High register holds the upper 16 bits of the 121th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_Low on page 17-791
The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address121_High on page 17-792
The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_Low on page 17-795
The MAC Address121 Low register holds the lower 32 bits of the 122th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address122_High on page 17-796
The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address122_Low on page 17-799
The MAC Address122 Low register holds the lower 32 bits of the 123th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address123_High on page 17-800
The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_Low on page 17-803
The MAC Address123 Low register holds the lower 32 bits of the 124th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address124_High on page 17-804
The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_Low on page 17-807
The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address125_High on page 17-808
The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low on page 17-811
The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address126_High on page 17-812
The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address126_Low on page 17-815
The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address127_High on page 17-816
The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_Low on page 17-819
The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700000
emac1	0xFF702000	0xFF702000

Offset: 0x0

MAC_Configuration Fields

Bit	Name	Description	Access	Reset
27	twokpe	When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.	RW	0x0
25	cst	When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. **Value** **Description** 0x0 Strip Ether Frames Off 0x1 Strip Ether Frames On	RW	0x0
24	tc	When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII. When this bit is reset, no such information is driven to the PHY. **Value** **Description** 0x1 Enables Transmission of duplex 0x0 Disables Transmission to Phy	RW	0x0
23	wd	When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes. **Value** **Description** 0x0 Enable MAC cutoff > 2048Bytes 0x1 Disable Watchdog	RW	0x0

Bit	Name	Description	Access	Reset
22	jd	When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission. **Value** **Description** 0x0 MAC cuts off TX > 2048 0x1 Jabber Timer Disabled	RW	0x0
21	be	When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. **Value** **Description** 0x0 Frame Burst Enable OFF 0x1 Frame Burst Enable ON	RW	0x0
20	je	When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status. **Value** **Description** 0x0 Report Jumbo Frame Error 0x1 Ignore Jumbo Frame Error	RW	0x0

Bit	Name	Description	Access	Reset
19:17	ifg	These bits control the minimum IFG between frames during transmission. In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 80 bit times (and above). **Value** — **Description** 0x0 — Inter Frame Gap 96 bit times 0x1 — Inter Frame Gap 88 bit times 0x2 — Inter Frame Gap 80 bit times 0x3 — Inter Frame Gap 72 bit times 0x4 — Inter Frame Gap 64 bit times 0x5 — Inter Frame Gap 56 bit times 0x6 — Inter Frame Gap 48 bit times 0x7 — Inter Frame Gap 40 bit times	RW	0x0
16	dcrs	When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. **Value** — **Description** 0x0 — MAC Tx Gen. Err. No Carrier 0x1 — MAC Tx Ignores (G)MII Crs Signal	RW	0x0
15	ps	This bit selects between GMII and MII **Value** — **Description** 0x0 — GMII 1000 Mbps 0x1 — MII 10/100 Mbps	RW	0x0

Bit	Name	Description	Access	Reset
14	fes	This bit selects the speed in the RGMII interface: * 0: 10 Mbps * 1: 100 Mbps This bit generates link speed encoding when TC (Bit 24) is set in the RGMII, SMII, or SGMII mode. **Value** **Description** 0x0 Speed = 10 Mbps 0x1 Speed = 100 Mbps	RW	0x0
13	do	When this bit is set, the MAC disables the reception of frames when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. **Value** **Description** 0x0 MAC Enables Reception of Frames 0x1 MAC Disables Reception of Frames	RW	0x0
12	lm	When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input is required for the loopback to work properly, because the Transmit clock is not looped-back internally. **Value** **Description** 0x0 Disable Loop Back 0x1 Enable Loop Back	RW	0x0
11	dm	When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. **Value** **Description** 0x1 MAC Full Duplex Enabled 0x0 MAC Full Duplex Disabled	RW	0x0

Bit	Name	Description	Access	Reset
10	ipc	When this bit is set, the MAC calculates the 16-bit ones complement of the ones complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. **Value** **Description** 0x1 Checksum Enabled 0x0 Checksum Disabled	RW	0x0
9	dr	When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode. **Value** **Description** 0x1 MAC attempts one transmission 0x0 MAC attempts retries per bl Field	RW	0x0
8	lud	This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface **Value** **Description** 0x0 Link Down 0x1 Link Up	RW	0x0

Bit	Name	Description	Access	Reset
7	acs	When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host. **Value** — **Description** 0x0 — Disable Automatic Pad CRC Stripping 0x1 — Enable Automatic Pad CRC Stripping	RW	0x0
6:5	bl	The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode. * 00: k = min (n, 10) * 01: k = min (n, 8) * 10: k = min (n, 4) * 11: k = min (n, 1) where n = retransmission attempt. The random integer r takes the value in the range 0 <= r < kth power of 2 **Value** — **Description** 0x0 — k = min (n, 10) 0x1 — k = min (n, 8) 0x2 — k = min (n, 4) 0x3 — k = min (n, 1)	RW	0x0

Bit	Name	Description	Access	Reset
4	dc	When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. **Value** **Description** 0x1 Deferral Check Enabled 0x0 Deferral Check Disabled	RW	0x0
3	te	When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames. **Value** **Description** 0x0 MAC transmit state machine disabled 0x1 MAC transmit state machine enabled	RW	0x0
2	re	When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII. **Value** **Description** 0x0 MAC receive state machine disabled 0x1 MAC receive state machine enabled	RW	0x0

Bit	Name	Description	Access	Reset
1:0	prelen	These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating **Value** **Description** 0x0 Preamble 7 Bytes 0x1 Preamble 5 Bytes 0x2 Preamble 3 Bytes	RW	0x0

MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Module Instance	Base Address	Register Address

MAC_Frame_Filter Fields

Bit	Name	Description	Access	Reset
31	ra	When this bit is set, the MAC Receiver block passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver block passes only those frames to the Application that pass the SA or DA address filter. **Value** — **Description** 0x0 — Receive All off 0x1 — Receive All On	RW	0x0
21	dntu	When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. **Value** — **Description** 0x0 — Forward all non-TCP or UDP over IP frames 0x1 — Drop non-TCP or UDP over IP frames	RW	0x0
20	ipfe	When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 filters. **Value** — **Description** 0x0 — Forward all frames irrespective of the match status of Layer 3 and Layer 4 filters 0x1 — Drop frames that do not match the enabled Layer 3 and Layer 4 filters	RW	0x0

Bit	Name	Description	Access	Reset
16	vtfe	When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag. **Value** **Description** 0x0 Forward all frames irrespective of the match status of the VLAN tag 0x1 Drop VLAN tagged frames that do not match the VLAN Tag comparison	RW	0x0
10	hpf	When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. **Value** **Description** 0x0 Hash or Perfect Filter off 0x1 Hash or Perfect Filter on	RW	0x0
9	saf	When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA Match bit of RxStatus Word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application and with the updated SA Match bit of the RxStatus depending on the SA address comparison. **Value** **Description** 0x0 SA Filter Off 0x1 SA Filter On	RW	0x0

Bit	Name	Description	Access	Reset
8	saif	When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter. When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter. **Value** — **Description** 0x0 — SA Nomatch Fail 0x1 — SA Match Fail	RW	0x0

Bit	Name	Description	Access	Reset
7:6	pcf	These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). * 00: MAC filters all control frames from reaching the application. * 01: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. * 10: MAC forwards all control frames to application even if they fail the Address Filter. * 11: MAC forwards control frames that pass the Address Filter. The following conditions should be true for the PAUSE control frames processing: * Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting Bit 2 (RFE) of Register 6 (Flow Control Register) to 1. * Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when Bit 3 (UP) of the Register 6 (Flow Control Register) is set. * Condition 3: The Type field of the received frame is 0x8808 and the OPCODE field is 0x0001. This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application). **Value** — **Description** 0x0 — MAC filters all control frames 0x1 — MAC forwards all control frames except PAUSE 0x2 — MAC forwards all control frames fail addrflt 0x3 — MAC forwards control frames that pass addrflt	RW	0x0
5	dbf	When this bit is set, the AFM block filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM block passes all received broadcast frames. **Value** — **Description** 0x0 — Pass All Broadcast Frames 0x1 — Filter All Broadcast Frames	RW	0x0

Bit	Name	Description	Access	Reset
4	pm	When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit. **Value** **Description** 0x0 Allows Filter of MC Frames 0x1 All Rcvd MC Frames Pass	RW	0x0
3	daif	When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed. **Value** **Description** 0x0 Normal Inverse Filter 0x1 Address Check Block Inverse Filter	RW	0x0
2	hmc	When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 MAC Filters with Compare 0x1 MAC Filters with Hash Table	RW	0x0
1	huc	When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 MAC Filters with Compare 0x1 MAC Filters with Hash Table	RW	0x0

Bit	Name	Description	Access	Reset
0	pr	When this bit is set, the Address Filter block passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set. **Value** **Description** 0x0 Clear SA DA Status Bits 0x1 All Incoming Frames Passed	RW	0x0

GMII_Address

The GMII Address register controls the management cycles to the external PHY through the management interface.

Module Instance	Base Address	Register Address

GMII_Address Fields

Bit	Name	Description	Access	Reset
15:11	pa	This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII block.	RW	0x0
10:6	gr	These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.	RW	0x0

Bit	Name	Description	Access	Reset
5:2	cr	The CSR Clock Range selection determines the frequency of the MDC clock according to the l3_sp_clk frequency used in your design. The suggested range of l3_sp_clk frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when l3_sp_clk is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Only use the values larger than 7 if the interfacing chips support faster MDC clocks. **Value** — **Description** 0x0 — l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42 0x1 — l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62 0x2 — l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16 0x3 — l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26 0x4 — l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102 0x5 — l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124 0x8 — l3_sp_clk/4 0x9 — l3_sp_clk/6 0xa — l3_sp_clk/8 0xb — l3_sp_clk/10 0xc — l3_sp_clk/12 0xd — l3_sp_clk/14 0xe — l3_sp_clk/16 0xf — l3_sp_clk/18	RW	0x0

Bit	Name	Description	Access	Reset
1	gw	When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register. **Value** — **Description** 0x0 — GMII Read Operation 0x1 — GMII Write Operation	RW	0x0
0	gb	This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present. **Value** — **Description** 0x0 — Not Busy 0x1 — Busy	RW	0x0

GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Module Instance	Base Address	Register Address

15:0	gd	This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700018
emac1	0xFF702000	0xFF702018

Offset: 0x18

Flow_Control Fields

Bit	Name	Description	Access	Reset
31:16	pt	This field holds the value to be used in the Pause Time field in the transmit control frame. Because the Pause Time bits are double-synchronized to the (G) MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.	RW	0x0
7	dzpq	When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. **Value** — **Description** 0x1 — Disable Auto Gen. of Zero-Quanta Pause 0x0 — Enable Auto Gen. of Zero-Quanta Pause	RW	0x0
5:4	plt	This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. **Value** — **Description** 0x0 — Pause time - 4 slot times 0x1 — Pause time - 28 slot times 0x2 — Pause time - 144 slot times 0x3 — Pause time - 256 slot times	RW	0x0

Bit	Name	Description	Access	Reset
3	up	When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard. **Value** **Description** 0x0 MAC Detects Pause MCA 0x1 MAC Detects Pause MCA and UCA	RW	0x0
2	rfe	When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled. **Value** **Description** 0x0 Decode Func. of Pause Frame Disabled 0x1 MAC decodes the received Pause	RW	0x0
1	tfe	In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled. **Value** **Description** 0x0 Transmit Flow Control Disable 0x1 Transmit Flow Control Enable	RW	0x0

Bit	Name	Description	Access	Reset
0	fca_bpa	This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set) , then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. **Value** **Description** 0x0 Pause Ctrl Frame and BPA off 0x1 Init Pause Ctrl Frame and BPA	RW	0x0

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

vl RW 0x0															

VLAN_Tag Fields

Bit	Name	Description	Access	Reset
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0
16	etv	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. **Value** — **Description** 0x0 — Disable 12-Bit VLAN Tag Compare 0x1 — Enable 12-Bit VLAN Tag Compare	RW	0x0

Bit	Name	Description	Access	Reset
15:0	vl	This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Module Instance	Base Address	Register Address

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset
19	lpitxa	This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. **Value** — **Description** 0x0 — LPI TX Automate Disabled 0x1 — LPI TX Automate Enabled	RW	0x0
18	plsen	This bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS TIMER. When set, the MAC uses the link-status bits of Register 54 (SGMII/RGMII/SMII Status Register) and Bit 17 (PLS) for the LPI LS Timer trigger. When cleared, the MAC ignores the link-status bits of Register 54 and takes only the PLS bit. **Value** — **Description** 0x0 — MAC Ignores Link Status Bits 0x1 — MAC Uses Link Status Bits	RW	0x0
17	pls	This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (okay) at least for the time indicated by the LPI LS TIMER. When set, the link is considered to be okay (up) and when reset, the link is considered to be down. **Value** — **Description** 0x0 — Link Down 0x1 — Link Up (okay)	RW	0x0

Bit	Name	Description	Access	Reset
16	lpien	When set, this bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. **Value** **Description** 0x0 MAC Transmitter exit LPI State 0x1 MAC Transmitter enters LPI State	RW	0x0
9	rlpist	When set, this bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC is not receiving LPI Pattern 0x1 MAC receiving LPI Pattern	RO	0x0
8	tlpist	When set, this bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC Transmitting LPI Pattern 0x1 MAC Transmitting LPI Pattern	RO	0x0
3	rlpiex	When set, this bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC RX receiving LPI Patterns 0x1 MAC RX Stopped receiving LPI Patterns	RO	0x0

Bit	Name	Description	Access	Reset
2	rlpien	When set, this bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC Receiver Not In LPI State 0x1 MAC Receiver In LPI State	RO	0x0
1	tlpiex	When set, this bit indicates that the MAC transmitter has exited the LPI state after the user has cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Non LPI State 0x1 MAC Transmitter Exited LPI State	RO	0x0
0	tlpien	When set, this bit indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Not in LPI State 0x1 MAC Transmitter Entered LPI State	RO	0x0

LPI_Timers_Control

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

LPI_Timers_Control Fields

Bit	Name	Description	Access	Reset
25:16	lst	This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	twt	This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Module Instance	Base Address	Register Address

Interrupt_Status Fields

Bit	Name	Description	Access	Reset
10	lpiis	This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared on reading Bit 0 of Register 12 (LPI Control and Status Register). In all other modes, this bit is reserved. **Value** — **Description** 0x0 — LPI Interrupt Status Disabled 0x1 — LPI Interrupt Status Enabled	RO	0x0
9	tsis	This bit is set when any of the following conditions is true: * The system time value equals or exceeds the value specified in the Target Time High and Low registers. * There is an overflow in the seconds register. * The Auxiliary snapshot trigger is asserted. This bit is cleared on reading Bit 0 of the Register 458 (Timestamp Status Register). When set, this bit indicates that the system time value is equal to or exceeds the value specified in the Target Time registers. In this mode, this bit is cleared after the completion of the read of this bit. In all other modes, this bit is reserved. **Value** — **Description** 0x0 — Timestamp Interrupt Status Disabled 0x1 — Timestamp Interrupt Status Enabled	RO	0x0
7	mmcrxipis	This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. **Value** — **Description** 0x0 — MMC Receive Checksum Offload Interrupt Status Disabled 0x1 — MMC Receive Checksum Offload Interrupt Status Enabled	RO	0x0

Bit	Name	Description	Access	Reset
6	mmctxis	This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. **Value** **Description** 0x0 MMC Transmit Interrupt Status Disabled 0x1 MMC Transmit Interrupt Status Enabled	RO	0x0
5	mmcrxis	This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. **Value** **Description** 0x0 MMC Receive Interrupt Status Disabled 0x1 MMC Receive Interrupt Status Enabled	RO	0x0
4	mmcis	This bit is set high when any of the Bits [7:5] is set high and cleared only when all of these bits are low. **Value** **Description** 0x0 MMC Interrupt Status Disabled 0x1 MMC Interrupt Status Enabled	RO	0x0
2	pcsancis	This bit is set when the Auto-negotiation is completed in the TBI, RTBI, or SGMII PHY interface (Bit 5 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation to the AN Status register. This bit is valid only when you select the SGMII PHY interface during operation.	RO	0x0
1	pcslchgis	This bit is set because of any change in Link Status in the TBI, RTBI, or SGMII PHY interface (Bit 2 in Register 49 (AN Status Register)). This bit is cleared when you perform a read operation on the AN Status register. This bit is valid only when you select the SGMII PHY interface during operation.	RO	0x0

Bit	Name	Description	Access	Reset
0	rgsmiiis	This bit is set because of any change in value of the Link Status of RGMII or SMII interface (Bit 3 in Register 54 (SGMII/RGMII/SMII Status Register)). This bit is cleared when you perform a read operation on the SGMII/RGMII/SMII Status Register. **Value** **Description** 0x0 Link No Change 0x1 Link Change	RO	0x0

Interrupt_Mask

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is sbd_intr_o.

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

MAC_Address2_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 3rd 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address3_High

The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address12_High

The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address12 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 16th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** — **Description** 0x0 — Second MAC address filtering disabled 0x1 — Second MAC address filtering enabled	RW	0x0

Bit	Name	Description	Access	Reset
30	sa	When this bit is enabled, the MAC Address15[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address15[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address15 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 16th 6-byte MAC address.	RW	0xFFFF

MAC_Address15_Low

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

0	lnkmod	This bit indicates the current mode of operation of the link Value: Description 0x0: Half Duplex 0x1: Full Duplex	RO	0x0

MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

Module Instance	Base Address	Register Address

MMC_Control Fields

Bit	Name	Description	Access	Reset
8	ucdbc	When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0

Bit	Name	Description	Access	Reset
5	cntprstlvl	When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. **Value** **Description** 0x0 Preset All Counters to almost-half 0x1 Present All Counters almost-full	RW	0x0
4	cntprst	When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. **Value** **Description** 0x0 Counters not preset 0x1 Counters preset to full or almost full	RW	0x0
3	cntfreez	When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. **Value** **Description** 0x0 Update MMC Counters 0x1 Freeze MMC counters to current value	RW	0x0

Bit	Name	Description	Access	Reset
2	rstonrd	When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read. **Value** **Description** 0x0 No reset after read 0x1 Reset after read	RW	0x0
1	cntstopro	When this bit is set, after reaching maximum value, the counter does not roll over to zero. **Value** **Description** 0x0 Counter Roll Over 0x1 Counter does not Roll Over	RW	0x0
0	cntrst	When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle. **Value** **Description** 0x0 Auto cleared after 1 clock cycle 0x1 All Counters Reset	RW	0x0

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Bit	Name	Description	Access	Reset
3	txmcgfis	This bit is set when the txmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 txmulticastframes_g < half max 0x1 txmulticastframes_g >= half max	RO	0x0
2	txbcgfis	This bit is set when the txbroadcastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 txbroadcastframes_g < half max 0x1 txbroadcastframes_g >= half max	RO	0x0
1	txgbfrmis	This bit is set when the txframecount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 txframecount_gb < half max 0x1 txframecount_gb >= half max	RO	0x0
0	txgboctis	This bit is set when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 txoctetcount_gb < half max 0x1 txoctetcount_gb >= half max	RO	0x0

MMC_Receive_Interrupt_Mask

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.

MMC_Receive_Interrupt_Mask Fields

Bit	Name	Description	Access	Reset
25	rxctrlfim	Setting this bit masks the interrupt when the rxctrlframes counter reaches half the maximum value, and also when it reaches the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
24	rxrcverrfim	Setting this bit masks the interrupt when the rxrcverror error counter reaches half the maximum value, and also when it reaches the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
23	rxwdogfim	Setting this bit masks the interrupt when the rxwatchdog counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
22	rxvlangbfim	Setting this bit masks the interrupt when the rxvlanframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
21	rxfovfim	Setting this bit masks the interrupt when the rxfifoo-verflow counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
20	rxpausfim	Setting this bit masks the interrupt when the rxpause-frames counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
19	rxorangefim	Setting this bit masks the interrupt when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
18	rxlenerfim	Setting this bit masks the interrupt when the rxlengtherror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
17	rxucgfim	Setting this bit masks the interrupt when the rxunicastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
16	rx1024tmaxoctgbfim	Setting this bit masks the interrupt when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
15	rx512t1023octgbfim	Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
14	rx256t511octgbfim	Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
13	rx128t255octgbfim	Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
12	rx65t127octgbfim	Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
11	rx64octgbfim	Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
10	rxosizegfim	Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	rxusizegfim	Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
8	rxjaberfim	Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
7	rxruntfim	Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
6	rxalgnerfim	Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
5	rxcrcerfim	Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	rxmcgfim	Setting this bit masks the interrupt when the rxmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
3	rxbcgfim	Setting this bit masks the interrupt when the rxbroadcastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
2	rxgoctim	Setting this bit masks the interrupt when the rxoctet-count_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
1	rxgboctim	Setting this bit masks the interrupt when the rxoctet-count_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
0	rxgbfrmim	Setting this bit masks the interrupt when the rxframe-count_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
1	rxipv4herfim	Setting this bit masks the interrupt when the rxipv4_hdrerr_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
0	rxipv4gfim	Setting this bit masks the interrupt when the rxipv4_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

L3_L4_Control0 Fields

Bit	Name	Description	Access	Reset
21	l4dpim0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	l4dpm0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM0) is set high.	RW	0x0
18	l4spm0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen0	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM0 or L4DPM0 bit is set high.	RW	0x0

Bit	Name	Description	Access	Reset
15:11	l3hdbm0	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
10:6	l3hsbm0	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
5	l3daim0	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM0) is set high.	RW	0x0
4	l3dam0	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 2 (L3SAM0) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
2	l3sam0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 4 (L3DAM0) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen0	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

Layer4_Address0

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	l4dpm2	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim2	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM2) is set high.	RW	0x0
18	l4spm2	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0

Bit	Name	Description	Access	Reset
16	l4pen2	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM2 or L4DPM2 bit is set high.	RW	0x0
15:11	l3hdbm2	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM2, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM2[1:0] and L3HSBM2 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM2 or L3SAM2 is set high.	RW	0x0
10:6	l3hsbm2	Layer 3 IP SA Higher Bits Match IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM2 or L3SAM2 is set high.	RW	0x0
5	l3daim2	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM2) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
4	l3dam2	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN2) is set, you should set either this bit or Bit 2 (L3SAM2) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim2	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM2) is set high.	RW	0x0
2	l3sam2	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN2) is set, you should set either this bit or Bit 4 (L3DAM2) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen2	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM2 or L3DAM2 bit is set high.	RW	0x0

Layer4_Address2

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

31:0	l3a33	When Bit 0 (L3PEN3) and Bit 2 (L3SAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN3) and Bit 4 (L3DAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control Fields

Bit	Name	Description	Access	Reset
25	atsen0	This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. **Value** **Description** 0x0 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is disabled. 0x1 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled.	RW	0x0
24	atsfc	When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. **Value** **Description** 0x0 Don't reset Auxiliary Snapshot FIFO pointers 0x1 Reset Auxiliary Snapshot FIFO pointers	RW	0x0

Bit	Name	Description	Access	Reset
18	tsenmacaddr	When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet. **Value** **Description** 0x0 DA MAC address doesn't filter PTP frames 0x1 DA MAC address filters PTP frames	RW	0x0
17:16	snaptypsel	These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.	RW	0x0
15	tsmstrena	When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. **Value** **Description** 0x0 Timestamp snapshot taken for messages relevant to slave node 0x1 Timestamp snapshot taken for messages relevant to master node	RW	0x0
14	tsevntena	When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling. **Value** **Description** 0x0 Timestamp snapshot disabled for event messages 0x1 Timestamp snapshot only for event messages	RW	0x0
13	tsipv4ena	When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv4 0x1 Process PTP packets in UDP over IPv4	RW	0x1

Bit	Name	Description	Access	Reset
12	tsipv6ena	When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv6 0x1 Process PTP packets in UDP over IPv6	RW	0x0
11	tsipena	When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets. **Value** **Description** 0x0 Don't process PTP packets in Ethernet frames 0x1 Process PTP packets in Ethernet frames	RW	0x0
10	tsver2ena	When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format. **Value** **Description** 0x0 PTP packets processed with 1588 version 1 format 0x1 PTP packets processed with 1588 version 2 format	RW	0x0
9	tsctrlssr	When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit. **Value** **Description** 0x0 Timestamp Low register rolls over at 0x7FFF_FFFF 0x1 Timestamp Low register rolls over at 1ns	RW	0x0

Bit	Name	Description	Access	Reset
8	tsenall	When set, the timestamp snapshot is enabled for all frames received by the MAC. **Value** **Description** 0x0 Timestamp snapshot disabled 0x1 Timestamp snapshot enabled	RW	0x0
5	tsaddreg	When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it. **Value** **Description** 0x0 Timestamp Addend register is not updated 0x1 Timestamp Addend register is updated	RW	0x0
4	tstrig	When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt. **Value** **Description** 0x0 Timestamp not generated 0x1 Timestamp generated	RW	0x0
3	tsupdt	When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register is not updated. **Value** **Description** 0x0 Timestamp not updated (added or subtracted) with values in Register 452 and Register 453 0x1 Timestamp updated (added or subtracted) with values in Register 452 and Register 453	RW	0x0

Bit	Name	Description	Access	Reset
2	tsinit	When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register can only be initialized. **Value** **Description** 0x0 Timestamp not initialized (overwritten) by values in Register 452 and Register 453 0x1 Timestamp initialized (overwritten) by values in Register 452 and Register 453	RW	0x0
1	tscfupdt	When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method. **Value** **Description** 0x0 Timestamp Coarse 0x1 Timestamp Fine	RW	0x0
0	tsena	When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set. **Value** **Description** 0x0 Timestamp not added 0x1 Timestamp added for transmit and receive	RW	0x0

Sub_Second_Increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

Timestamp_Status Fields

Bit	Name	Description	Access	Reset
29:25	atsns	This field indicates the number of Snapshots available in the FIFO. A value of 16 (equal to the depth of the FIFO) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.	RO	0x0
24	atsstm	This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. **Value** **Description** 0x0 Not Active 0x1 Aux timestamp snapshot full	RO	0x0
19:16	atsstn	These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: * Bit 16: Auxiliary trigger 0 * Bit 17: Auxiliary trigger 1 * Bit 18: Auxiliary trigger 2 * Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken.	RO	0x0
3	tstrgterr	This bit is set when the target time, being programmed in Target Time Registers, is already elapsed. This bit is cleared when read by the application. **Value** **Description** 0x0 When Read resets 0x1 Target Time Elapsed -Reg455 and Reg456	RO	0x0
2	auxtstrig	This bit is set high when the auxiliary snapshot is written to the FIFO. **Value** **Description** 0x0 System Time 0x1 System Time is >= Reg455 and Reg456	RO	0x0

Bit	Name	Description	Access	Reset
1	tstargt	When set, this bit indicates that the value of system time is greater or equal to the value specified in the Register 455 (Target Time Seconds Register) and Register 456 (Target Time Nanoseconds Register). **Value** **Description** 0x0 System Time 0x1 System Time is >= Reg455 and Reg456	RO	0x0
0	tssovf	When set, this bit indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. **Value** **Description** 0x0 No Overflow 0x1 Seconds Overflow	RO	0x0

PPS_Control Fields

Bit	Name	Description	Access	Reset
6:5	trgtmodsel0	This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal **Value** **Description** 0x0 Target Time regs generate interrupt event. 0x2 Target Time gen. interr event and sig pps0 0x3 Target Time No inter just start and stop sig pps0	RW	0x0
4	ppsen0	When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD. **Value** **Description** 0x0 Bits[3:0] function as ppsctrl0 0x1 Bits[3:0] function as ppscmd	RW	0x0
3:0	ppsctrl_ppscmd	PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz.	RW	0x0

Bit	Name	Description	Access	Reset
		Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: * 0000: No Command * 0001: START Single Pulse This command generates single pulse		

Bit	Name	Description	Access	Reset
		rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. * 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. * 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. * 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. * 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). * 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. * 0111-1111: Reserved		

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

ppswidth RW 0x0															

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	ppswidth	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	RW	0x0

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address18_High

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address21_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 22th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address22_High

The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 31th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address30[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address30[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address30 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 31th 6-byte MAC address.	RW	0xFFFF

MAC_Address30_Low

The MAC Address30 Low register holds the lower 32 bits of the 31th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700874
emac1	0xFF702000	0xFF702874

MAC_Address31_High

The MAC Address31 High register holds the upper 16 bits of the 32th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address35_High

The MAC Address35 High register holds the upper 16 bits of the 36th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address35 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address39_High

The MAC Address39 High register holds the upper 16 bits of the 40th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address39 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_High

The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_High

The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_High

The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_High

The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_High

The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 63th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address63_High

The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_High

The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address71_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 72th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address71[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address71[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address71 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 72th 6-byte MAC address.	RW	0xFFFF

MAC_Address71_Low

The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

MAC_Address72_High

The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_High

The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_High

The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_High

The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address92_High

The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_High

The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address100_High

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_High

The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address107_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 108th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address108_High

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700AE0
emac1	0xFF702000	0xFF702AE0

MAC_Address112_High

The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address117_High

The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 121th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address120[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address120[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address120 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 121th 6-byte MAC address.	RW	0xFFFF

MAC_Address120_Low

The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700B44

MAC_Address121_High

The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

31	ae	When this bit is enabled, the address filter block uses the 125th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address124[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address124[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address124 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 125th 6-byte MAC address.	RW	0xFFFF

MAC_Address124_Low

The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

MAC_Address125_High

The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

Bus_Mode on page 17-822
The Bus Mode register establishes the bus operating modes for the DMA.

Transmit_Poll_Demand on page 17-825
The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Receive_Poll_Demand on page 17-826
The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Descriptor_List_Address on page 17-827
The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 17-828
The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 17-828
The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 17-834
The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 17-840
The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 17-844
The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 17-845
This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 17-846
The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 17-849
This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Current_Host_Transmit_Descriptor on page 17-850
The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 17-850
The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 17-851
The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 17-851
The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 17-852
This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

Module Instance	Base Address	Register Address

Bus_Mode Fields

Bit	Name	Description	Access	Reset
25	aal	When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. **Value** — **Description** 0x0 — No Address-Aligned Beats 0x1 — Address-Aligned Beats (dependent on FB)	RW	0x0

Bit	Name	Description	Access	Reset
24	eightxpbl	When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. **Value** **Description** 0x0 Non Multiply Mode 0x1 Multiplies PBL value by 8	RW	0x0
23	usp	When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines. **Value** **Description** 0x0 Configures TX RX DMA to PBL 0x1 Configures TX DMA to PBL	RW	0x0
22:17	rpbl	This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high. **Value** **Description** 0x1 Beats Trans. in one Rx DMA Transaction 0x2 Beats Trans. in one Rx DMA Transaction 0x4 Beats Trans. in one Rx DMA Transaction 0x8 Beats Trans. in one Rx DMA Transaction 0x10 Beats Trans. in one Rx DMA Transaction 0x20 Beats Trans. in one Rx DMA Transaction	RW	0x1

Bit	Name	Description	Access	Reset
16	fb	This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the AXI interface uses FIXED bursts during the start of the normal burst transfers. When reset, the AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEFINED) of the AXI Bus Mode register. **Value** — **Description** 0x0 — SINGLE or INCR Burst 0x1 — FIXED Burst (1, 4, 8, or 16)	RW	0x0
13:8	pbl	These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.	RW	0x1
7	atds	When set, the size of the alternate (enhanced) descriptor increases to 32 bytes (8 DWORDS). When clear, the alternate (enhanced) descriptor size is 16 bytes (4 DWORDS). **Value** — **Description** 0x0 — Descriptor size is 16 bytes (4 DWORDS) 0x1 — Descriptor size is 32 bytes (8 DWORDS)	RW	0x0

Bit	Name	Description	Access	Reset
6:2	dsl	This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.	RW	0x0
0	swr	When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the EMAC clock domains. Before reprogramming any register of the EMAC, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion. **Value** **Description** 0x0 MAC DMA Controller Clears Logic 0x1 MAC DMA Controller Resets Logic	RW	0x1

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Transmit_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Module Instance	Base Address	Register Address

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Bit	Name	Description	Access	Reset
16	nis	Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0
15	ais	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0
14	eri	This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.	RW	0x0
13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0

Bit	Name	Description	Access	Reset
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0

Bit	Name	Description	Access	Reset
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Module Instance	Base Address	Register Address

Operation_Mode Fields

Bit	Name	Description	Access	Reset
26	dt	When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. **Value** **Description** 0x0 All Error Frames Dropped 0x1 MAC does not drop frame with errors	RW	0x0

Bit	Name	Description	Access	Reset
25	rsf	When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits. **Value** **Description** 0x0 Rx Fifo cut-through mode 0x1 Read Rx FIFO only after complete frame	RW	0x0
24	dff	When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. **Value** **Description** 0x0 Rx DMA Flushed 0x1 Rx DMA not Flushed	RW	0x0
21	tsf	When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped. **Value** **Description** 0x0 Tx Does not Start with Full Frame 0x1 Tx Start with Full Frame	RW	0x0

Bit	Name	Description	Access	Reset
20	ftf	When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock is required to be active. **Value** — **Description** 0x0 — Tx FIFO Data not Flushed 0x1 — TX FIFO Data Flushed	RW	0x0
16:14	ttc	These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. **Value** — **Description** 0x0 — MTL Transmit FIFO Threshold 64 0x1 — MTL Transmit FIFO Threshold 128 0x2 — MTL Transmit FIFO Threshold 192 0x3 — MTL Transmit FIFO Threshold 256 0x4 — MTL Transmit FIFO Threshold 40 0x5 — MTL Transmit FIFO Threshold 32 0x6 — MTL Transmit FIFO Threshold 24 0x7 — MTL Transmit FIFO Threshold 16	RW	0x0

Bit	Name	Description	Access	Reset
13	st	When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state. **Value** — **Description** 0x0 — Transmission Stopped State 0x1 — Transmission in Run State	RW	0x0
12:11	rfd	These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. The de-assertion is effective only after flow control is asserted. **Value** — **Description** 0x0 — Full minus 1 KB 0x1 — Full minus 2 KB 0x2 — Full minus 3 KB 0x3 — Full minus 4 KB	RW	0x0

Bit	Name	Description	Access	Reset
10:9	rfa	These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. These values only apply to the Rx FIFO when the EFC bit is set high. **Value** **Description** 0x0 Full minus 1 KB 0x1 Full minus 2 KB 0x2 Full minus 3 KB 0x3 Full minus 4 KB	RW	0x0
8	efc	When this bit is set, the flow control signal operation based on the fill-level of Rx FIFO is enabled. When reset, the flow control operation is disabled. **Value** **Description** 0x0 Rx FIFO Fill Level Disabled 0x1 Rx FIFO Fill Level Enabled Ctrl	RW	0x0
7	fef	When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA. **Value** **Description** 0x0 Drops Frames with error status 0x1 Forward all Frames(except runt)	RW	0x0

Bit	Name	Description	Access	Reset
6	fuf	When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01. **Value** **Description** 0x0 Drops Frames less than 64Bytes 0x1 Forward Frames with no errors	RW	0x0
4:3	rtc	These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. **Value** **Description** 0x0 MTL Rcv Fifo threshold level 64 0x1 MTL Rcv Fifo threshold level 32 0x2 MTL Rcv Fifo threshold level 96 0x3 MTL Rcv Fifo threshold level 128	RW	0x0
2	osf	When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained. **Value** **Description** 0x0 DMA Does Not Process second frame 0x1 DMA Processes second frame	RW	0x0

Bit	Name	Description	Access	Reset
1	sr	When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state. **Value** **Description** 0x0 Rx DMA operation is stopped 0x1 Rx DMA operation is started	RW	0x0

Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Module Instance	Base Address	Register Address

5	une	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Underflow Interrupt is enabled. When this bit is reset, the Underflow Interrupt is disabled. **Value** **Description** 0x0 Underflow Interrupt Disabled 0x1 Underflow Interrupt Enabled	RW	0x0
4	ove	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Receive Overflow Interrupt is enabled. When this bit is reset, the Overflow Interrupt is disabled. **Value** **Description** 0x0 Transmit Overflow Interrupt Disabled 0x1 Transmit Overflow Interrupt Enabled	RW	0x0

Bit	Name	Description	Access	Reset
3	tje	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Jabber Timeout Interrupt is enabled. When this bit is reset, the Transmit Jabber Timeout Interrupt is disabled. **Value** **Description** 0x0 Transmit Jabber Timeout Interrupt Disabled 0x1 Transmit Jabber Timeout Interrupt Enabled	RW	0x0
2	tue	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Buffer Unavailable Interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable Interrupt is disabled. **Value** **Description** 0x0 Transmit Buffer Unavailable Interrupt Disabled 0x1 Transmit Buffer Unavailable Interrupt Enabled	RW	0x0
1	tse	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmission Stopped Interrupt is enabled. When this bit is reset, the Transmission Stopped Interrupt is disabled. **Value** **Description** 0x0 Transmit Stopped Interrupt Disabled 0x1 Transmit Stopped Interrupt Enabled	RW	0x0
0	tie	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. **Value** **Description** 0x0 Transmit Interrupt Disabled 0x1 Transmit Interrupt Enabled	RW	0x0

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701020
emac1	0xFF702000	0xFF703020

Offset: 0x1020

Receive_Interrupt_Watchdog_Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address

Document Revision History

Table 17-27: Document Revision History

Date	Version	Changes

November 2015	2015.11.02	• Added the following subsections in the "Layer 3 and Layer 4 Filters" section:
		  • Layer 3 and Layer 4 Filters Register Set
		  • Layer 3 Filtering
		  • Layer 4 Filtering

Date	Version	Changes
May 2015	2015.05.04	• Corrected IEEE 1588 timestamp resolution in the "EMAC Block Diagram and System Integration" section and the "IEEE 1588-2002 Timestamps" section • Added reset pulse width for `rst_clk_tx_n_o` and `rst_clk_rx_n_o` in the "FPGA EMAC I/O signals" section • Added subsections "Ordinary Clock," "Boundary Clock," "End-to-End Transparent Clock" and "Peer-to-Peer Transparent Clock" in the "Clock Type" section
December 2014	2014.12.15	• Updated *EMAC Block Diagram and System Integration* section with new diagram and information. • Added *Signal Descriptions* section. • Added *EMAC Internal Interfaces* section. • Added *TX FIFO* and *RX FIFO* subsection to the *Transmit and Receive Data FIFO Buffers* section. • Updated *Descriptor Overview* section to clarify support for only enhanced (alternate) descriptors. • Added *Destination and Source Address Filtering Summary* in *Frame Filtering* Section. • Added *Clock Structure* sub-section to *Clocks and Resets* section • Added *System Level EMAC Configuration Registers* section in *Ethernet Programming Model* • Added *EMAC Interface Initialization for FPGA GMII/MII Mode* section in Ethernet Programming Model • Added *EMAC Interface Initialization for RGMII/RMII Mode* section in Ethernet Programming Model • Corrected *DMA Initialization* and *EMAC Initialization and Configuration* titles to appear on correct initialization information • Removed duplicate programming information for DMA • Added *Taking the Ethernet MAC Out of Reset* section.
June 2014	2014.06.30	Updated EMAC to RGMII Interface table with EMAC Port names Updated EMAC to FPGA PHY Interface table with Signal names Updated EMAC to FPGA IEEE1588 Timestamp Interface with Signal names Added Address Map and Register Descriptions
February 2014	2014.02.28	ECC updates.
December 2013	1.4	Maintenance release.
November 2012	1.3	• Expanded shared memory block table. • Added CSEL tables. • Additional minor updates.
June 2012	1.2	Updated the HPS boot and FPGA configuration sections.

USB 2.0 OTG Controller 18

2015.11.02

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys® (†)DesignWare® Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Can operate in Host or Device mode
- Supports multi-point applications with hub and split support
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)

  Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.
- Integrated scatter-gather DMA supports moving data between memory and the controller
- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
  - Control transfers
  - Bulk transfers
  - Isochronous transfers
  - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

  Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports up to 16 bidirectional endpoints, including control endpoint 0

  Note: Only seven periodic device IN endpoints are supported.
- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- 8-bit ULPI PHY data width
- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
  - PHY clock gating support
  - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

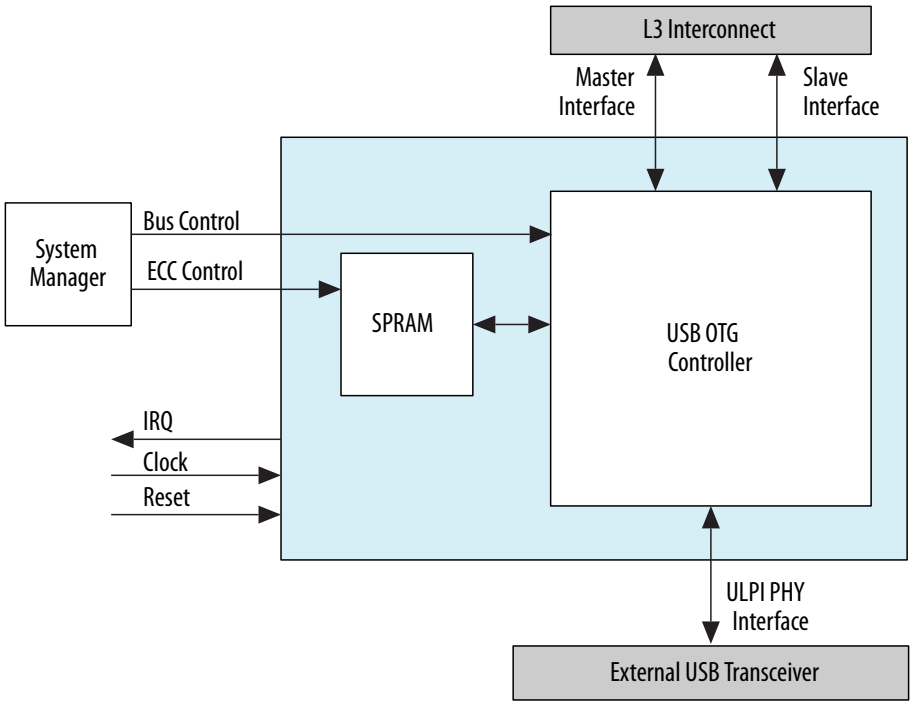
PHYs that support LPM mode may not function properly with the USB controller due to a timing issue. It is recommended that designers use the MicroChip USB3300 PHY device that has been proven to be successful on the development board.

Refer to the *Arria V Device Datasheet* for specific timing information.

USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.



The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB controller will only use Direct Shared IO 48.

USB 2.0 ULPI PHY Signal Description

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

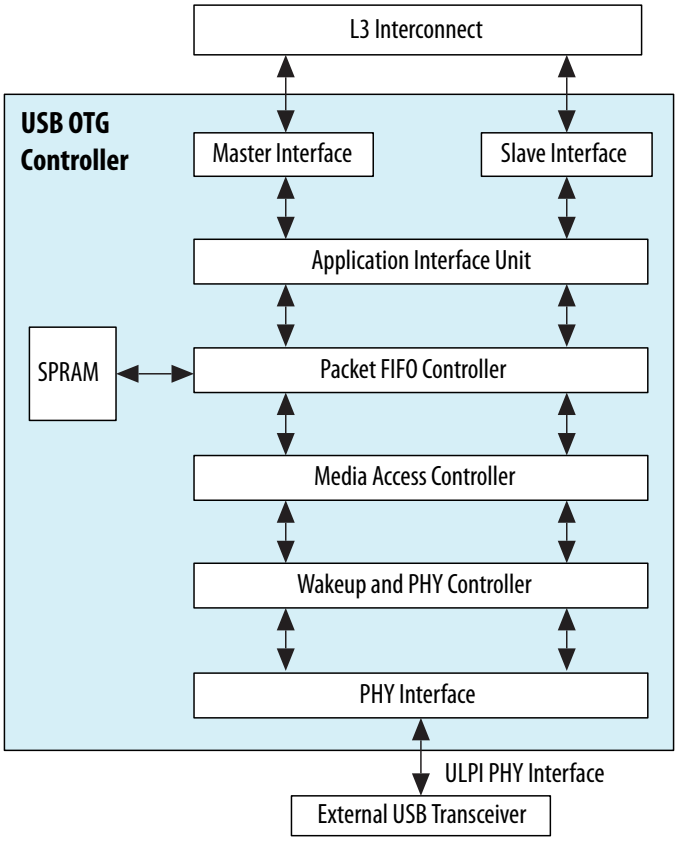
Port Name	Bit Width	Direction	Description
`ulpi_clk`	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
`ulpi_dir`	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
`ulpi_nxt`	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
`ulpi_stp`	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
`ulpi_data[7:0]`	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.



Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the SPRAM.

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (`en`) bit in the USB0 or USB1 RAM ECC Enable Register (`usb0` or `usb1`), in the ECC Management Register Group (`eccgrp`). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

DMA

The DMA has two modes of operation. You program your software to select between scatter-gather DMA mode or buffer DMA mode depending on the controllers function.

If the controller is functioning as a generic root hub, you should program your software to select the buffer DMA mode that supports split transfers.

If generic root hub functionlaity is not required, or if the controller is configured in Device mode, you can program your software to select scatter-gather DMA mode.

If you wish to dynamically switch the mode of operation based on the queried device status or capability, your software driver must cleanly switch between the two modes of operation. For example, you may want the controller to default to scatter-gather DMA mode and only change mode when it detects a generic HUB with fast-speed and low-speed capability. Some basic requirements for switching include:

- A soft reset must be issued before changing modes.
- If buffer DMA mode is selected, then the Host mode periodic request queue depth must not be set to 16.
- Devices must be re-enumerated.

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 x 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the ulpi_clk clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the ulpi_stp signal. The PHY outputs a clock when it sees the ulpi_stp signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the ulpi_stp signal. As a result, the ulpi_clk clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two usb_mp_c lk cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Modules Requiring Software Deassert on page 3-9

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode

Condition	Mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts

Condition	Mode
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtpwr`) bit to 1 in the Host Port Control and Status Register (`hprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

The controller waits for a connection to be detected on the USB link.

2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDe t`) bit in `hprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtenchng`) and Port Speed (`prtspd`) bits, in `hprt`, are set to reflect the enumerated speed of the device that attached.

   At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

   The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`host grp`) group.
7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:

   a. Receive FIFO Size Register (`grxfsiz`)—selects the size of the receive FIFO buffer
   b. Non-periodic Transmit FIFO Size Register (`gnptxfsiz`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
   c. Host Periodic Transmit FIFO Size Register (`hptxfsiz`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dcfg`) in the Device Mode Registers (`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.
2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consists of the following region:

USB OTG Controller Module Registers Address Map on page 18-17
Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessedin both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

Related Information

- **Introduction to the Hard Processor System** on page 1-1
  The base addresses of all modules are listed in the *Introduction to the Hard Processor System* chapter.
- **http://www.altera.com/literature/hb/arria-v/hps.html**

USB OTG Controller Module Registers Address Map

Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessedin both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

Direct_FIFO	This address space is allocated for directly accessing the data FIFO for debugging purposes.	0x20000	0x3FFFF

Global Registers Register Descriptions

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Offset: 0x0

gotgctl on page 18-41
The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgint on page 18-46
The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

gahbcfg on page 18-48
This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

gusbcfg on page 18-52
This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

grstctl on page 18-57
The application uses this register to reset various hardware features inside the core

gintsts on page 18-61
This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk on page 18-70
This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr on page 18-75
A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsp on page 18-76
A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register'ss reset value before configuring the core because the read value is "X" in the simulation.

grxfsiz on page 18-77
The application can program the RAM size that must be allocated to the RxFIFO.

gnptxfsiz on page 18-78
The application can program the RAM size and the memory start address for the Non-periodic TxFIFO. The fields of this register change, depending on host or device mode.

gnptxsts on page 18-79
In Device mode, this register is valid only in Shared FIFO operation. It contains the free space information for the Non-periodic TxFIFO and the Nonperiodic Transmit RequestQueue

gpvndctl on page 18-80
The application can use this register to access PHY registers. for a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access

ggpio on page 18-82
The application can use this register for general purpose input/output ports or for debugging.

guid on page 18-83
This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

gsnpsid on page 18-84
This read-only register contains the release number of the core being used.

ghwcfg1 on page 18-84
This register contains the logical endpoint direction(s).

ghwcfg2 on page 18-85
This register contains configuration options.

ghwcfg3 on page 18-89
This register contains the configuration options.

ghwcfg4 on page 18-91
This register contains the configuration options.

gdfifocfg on page 18-96
Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

hptxfsiz on page 18-96
This register holds the size and the memory start address of the Periodic TxFIFO

dieptxf1 on page 18-97
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf2 on page 18-98
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf3 on page 18-99
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf4 on page 18-99
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf5 on page 18-100
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf6 on page 18-101
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf7 on page 18-101
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf8 on page 18-102
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf9 on page 18-103
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf10 on page 18-104
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf11 on page 18-104
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf12 on page 18-105
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf13 on page 18-106
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf14 on page 18-106
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf15 on page 18-107
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

gotgctl

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgctl Fields

Bit	Name	Description	Access	Reset
20	otgver	Indicates the OTG revision. In OTG Version 1.3. the core supports Data line pulsing and VBus pulsing for SRP. In OTG Version 2.0 the core supports only Data line pulsing for SRP. **Value** **Description** 0x0 OTG Version 1.3. In this version the core supports Data line 0x1 OTG Version 2.0. In this version the core supports only Data line pulsing for SRP	RW	0x0

Bit	Name	Description	Access	Reset
19	bsesvld	Mode: Device only. Indicates the Device mode transceiver status. In OTG mode, you can use this bit to determine IF the device is connected or disconnected. If you do not enable OTG features (such as SRP and HNP), the read reset value will be 1. The vbus assigns the values internally for non-SRP or non-HNP configurations. **Value** — **Description** 0x0 — B-session is not valid 0x1 — B-session is valid	RO	0x0
18	asesvld	Mode: Host only. Indicates the Host mode transceiver status. If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non-SRP or non-HNP configurations. **Value** — **Description** 0x0 — A-session is not valid 0x1 — A-session is valid	RO	0x0
17	dbnctime	Mode: Host only. Indicates the debounce time of a detected connection. **Value** — **Description** 0x0 — Long debounce time, used FOR physical connections (100 ms + 2.5 s) 0x1 — Short debounce time, used FOR soft connections (2.5 s	RO	0x0
16	conidsts	Mode: Host and Device. Indicates the connector ID status on a connect event.This bit is valid only for Host and Device mode. **Value** — **Description** 0x0 — The DWC_otg core is in A-Device mode 0x1 — The otg core is in B-Device mode	RO	0x1

Bit	Name	Description	Access	Reset
11	devhnpen	Mode: Device only. The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host. **Value** **Description** 0x0 HNP is not enabled in the application 0x1 HNP Enabled	RW	0x0
10	hstsethnpen	Mode: Host only. The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device. **Value** **Description** 0x0 Host Set HNP is not enabled 0x1 Host Set HNP is enabled	RW	0x0
9	hnpreq	Mode: Device only. The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET.The core clears this bit when the HstNegSucStsChng bit iscleared. **Value** **Description** 0x0 No HNP request 0x1 HNP request	RW	0x0
8	hstnegscs	Mode: Device only. Host Negotiation Success (HstNegScs) The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPReq) bit in this register is SET. **Value** **Description** 0x0 Host negotiation failure 0x1 Host negotiation success	RO	0x0

Bit	Name	Description	Access	Reset
7	bvalidovval	This bit is used to set Override value for Bvalid signalwhen GOTGCTL.BvalidOvEn is set. **Value** **Description** 0x0 Bvalid value when GOTGCTL.AvalidOvEn =1 0x1 Bvalid value when GOTGCTL.AvalidOvEn =1	RW	0x0
6	bvalidoven	This bit is used to enable/disable the software to override the Bvalid signal using the GOTGCTL.BvalidOvVal. **Value** **Description** 0x0 Override is disabled and bvalid signal from the respective PHY selected is used internally by the core 0x1 Internally Bvalid received from the PHY is overridden with GOTGCTL.BvalidOvVal	RW	0x0
5	avalidovval	This bit is used to set Override value for Avalid signal when GOTGCTL.BvalidOvEn is set. **Value** **Description** 0x0 Avalid value is 1'b0 when GOTGCTL.BvalidOvEn =1 0x1 Avalid value is 1'b1 when GOTGCTL.BvalidOvEn =1	RW	0x0
4	avalidoven	This bit is used to enable/disable the software to override the Avalid signal using the GOTGCTL.AvalidOvVal. **Value** **Description** 0x0 Override is disabled and Avalid signal from the respective PHY is used internally by the core. 0x1 Internally Avalid received from the PHY is overridden with GOTGCTL.AvalidOvVa	RW	0x0

Bit	Name	Description	Access	Reset
3	vbvalidovval	This bit is used to set Override value for vbus valid signal when GOTGCTL.VbvalidOvEn is set. **Value** **Description** 0x0 vbusvalid value when GOTGCTL.VbvalidOvEn = 1 0x1 vbusvalid value when GOTGCTL.VbvalidOvEn is 1	RW	0x0
2	vbvalidoven	This bit is used to enable/disable the software to override the vbus-valid signal using the GOTGCTL.vbvalidOvVal.. **Value** **Description** 0x0 Override is disabled and bvalid signal from the respective PHY selected is used internally by the force 0x1 The vbus-valid signal received from the PHY is overridden with GOTGCTL.vbvalidOvVal	RW	0x0
1	sesreq	The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET. The core clears this bit when the HstNegSucStsChng bit is cleared. If you use the USB 1.1 Full-Speed Serial Transceiver interface to initiate the session request, the application must wait until the VBUS discharges to 0.2 V, after the B-Session Valid bit in this register (GOTGCTL.BSesVld) is cleared. This discharge time varies between different PHYs and can be obtained from the PHY vendor. **Value** **Description** 0x0 No session request 0x1 Session request	RW	0x0

Bit	Name	Description	Access	Reset
0	sesreqscs	This bit is set when a session request initiation is successful. This bit is valid only For Device Only configuration when OTG_MODE == 3 or OTG_ MODE == 4. Applies for device only. **Value** **Description** 0x0 Session request failure 0x1 Session request success	RO	0x0

gotgint

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

Module Instance	Base Address	Register Address

gotgint Fields

Bit	Name	Description	Access	Reset
19	dbncedone	Mode: Host only. The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is SET in the Core USB Configuration register (GUSBCFG.HNPCap or GUSBCFG.SRPCap, respectively). This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Change 0x1 Debounce completed	RO	0x0
18	adevtoutchg	Mode:Host and Device. The core sets this bit to indicate that the A-device has timed out WHILE waiting FOR the B-device to connect. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Change 0x1 A-Device Timeout	RO	0x0
17	hstnegdet	Mode:Host and Device. The core sets this bit when it detects a host negotiation request on the USB. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Change 0x1 Host Negotiation Detected	RO	0x0

Bit	Name	Description	Access	Reset
9	hstnegsucstschng	Mode: Host and Device. The core sets this bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit of the OTG Control and Status register (GOTGCTL.HstNegScs) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Change 0x1 Host Negotiation Status Change	RO	0x0
8	sesreqsucstschng	Mode: Host and Device. The core sets this bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (GOTGCTL.SesReqScs) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No change 0x1 Session Request Status	RO	0x0
2	sesenddet	Mode:Host and Device.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 Non Active State 0x1 Set when utmisrp_bvalid signal is deasserted	RO	0x0

gahbcfg

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

Module Instance	Base Address	Register Address

gahbcfg Fields

Bit	Name	Description	Access	Reset
22	notialldmawrit	This bit is programmed to enable the System DMA Done functionality for all the DMA write Transactions corresponding to the Channel/Endpoint. This bit is valid only when GAHBCFG.RemMemSupp is set to 1. **Value** — **Description** 0x1 — HSOTG core asserts int_dma_req for all the DMA write transactions on the AHB interface along with int_dma_done, chep_last_transact and chep_number signal informations. The core waits for sys_dma_done signal for all the DMA write transactions in order to complete the transfer of a particular Channel/Endpoint 0x0 — HSOTG core asserts int_dma_req signal only for the last transaction of DMA write transfer corresponding to a particular Channel/Endpoint. Similarly, the core waits for sys_dma_done signal only for that transaction of DMA write to complete the transfer of a particular Channel/Endpoint	RW	0x0

Bit	Name	Description	Access	Reset
21	remmemsupp	This bit is programmed to enable/disable the functionality to wait for the system DMA Done Signal for the DMA Write Transfers. -The int_dma_req output signal is asserted when HSOTG DMA starts write transfer to the external memory. When the core is done with the Transfers it asserts int_dma_done signal to flag the completion of DMA writes from HSOTG. The core then waits for sys_dma_done signal from the system to proceed further and complete the Data Transfer corresponding to a particular Channel/Endpoint. -The int_dma_req and int_dma_done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as wait for the system DMA Done Signal for the DMA Write Transfers the DMA write transfer is done at the HSOTG Core Boundary and it doesn't wait for the sys_dma_done signal to complete the DATA **Value** **Description** 0x0 Disable wait for system DMA Done Signal 0x1 Enable wait for the system DMA Done Signal for the DMA Write Transfers	RW	0x0
8	ptxfemplvl	Mode:Host only. Indicates when the Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.PTxFEmp) is triggered. This bit is used only in Slave mode. **Value** **Description** 0x0 GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is half empty 0x1 GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is completely empty	RW	0x0

Bit	Name	Description	Access	Reset
7	nptxfemplvl	Mode:Host and device. This bit is used only in Slave mode. In host mode and with Shared FIFO with device mode, this bit indicates when the Non-Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.NPTxFEmp) is triggered. With dedicated FIFO in device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (DIEPINTn.TxFEmp) is triggered. Host mode and with Shared FIFO with device mode: **Value** — **Description** 0x0 — DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is half empty or DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is half empty 0x1 — GINTSTS.NPTxFEmp interrupt indicates that the Non-Periodic TxFIFO is completely empty or DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is completely empty	RW	0x0
5	dmaen	Mode:Host and device. Enables switching from DMA mode to slave mode. **Value** — **Description** 0x0 — Core operates in Slave mode 0x1 — Core operates in a DMA mode	RW	0x0
4:1	hbstlen	Mode:Host and device. This field is used in Internal DMA modes. **Value** — **Description** 0x0 — 1 word or single 0x1 — 4 word or incr 0x2 — 8 word 0x3 — 16 word or incr4 0x4 — 32 word 0x5 — 64 word or incr8 0x6 — 128 word 0x7 — 256 word or incr16 0x8 — Others reserved	RW	0x0

Bit	Name	Description	Access	Reset
0	glblintrmsk	Mode: Host and device. The application uses this bit to mask or unmask the interrupt line assertion to itself. Irrespective of this bits setting, the interrupt status registers are updated by the core. **Value** **Description** 0x0 Mask the interrupt assertion to the application 0x1 Unmask the interrupt assertion to the application.	RW	0x0

gusbcfg

This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

gusbcfg Fields

Bit	Name	Description	Access	Reset
31	corrupttxpkt	Mode: Host and device. This bit is for debug purposes only. Never Set this bit to 1. The application should always write 0 to this bit. **Value** **Description** 0x0 Normal Mode 0x1 Debug Mode	WO	0x0
30	forcedevmode	Mode:Host and device. Writing a 1 to this bit forces the core to device mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro-sec is sufficient. **Value** **Description** 0x0 Normal Mode 0x1 Force Device Mode	RW	0x0
29	forcehstmode	Mode:Host and device. Writing a 1 to this bit forces the core to host mode After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro-sec is sufficient. **Value** **Description** 0x0 Normal Mode 0x1 Force Host Mode	RW	0x0
28	txenddelay	Mode: Device only. Set to non UTMI+. **Value** **Description** 0x0 Normal Mode	RW	0x0
25	ulpi	Mode:Host only. Controls circuitry built into the PHY for protecting the ULPI interface when the link tri-states STP and data. Any pull-ups or pull-downs employed by this feature can be disabled. **Value** **Description** 0x0 Enables the interface protect circuit 0x1 Disables the interface protect circuit	RW	0x0

Bit	Name	Description	Access	Reset
24	indicator	Mode:Host only. Controls wether the Complement Output is qualified with the Internal Vbus Valid comparator before being used in the Vbus State in the RX CMD. **Value** **Description** 0x0 Complement Output signal is qualified with the Internal VbusValid comparator 0x1 Complement Output signal is not qualified with the Internal VbusValid comparator	RW	0x0
23	complement	Mode:Host only. Controls the PHY to invert the ExternalVbusIndicator inputsignal, generating the ComplementOutput. Please refer to the ULPI Spec for more detail. **Value** **Description** 0x0 PHY does not invert ExternalVbusIndicator signal 0x1 PHY does invert ExternalVbusIndicator signal	RW	0x0
22	termseldlpulse	Mode:Device only. This bit selects utmi_termselect to drive data line pulse during SRP. **Value** **Description** 0x0 Data line pulsing using utmi_txvalid 0x1 Data line pulsing using utmi_termsel	RW	0x0
21	ulpiextvbusindicator	Mode:Host only. This bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator. **Value** **Description** 0x0 PHY uses internal VBUS valid comparator 0x1 PHY uses external VBUS valid comparator	RW	0x0
20	ulpiextvbusdrv	Mode:Host only. This bit selects between internal or external supply to drive 5V on VBUS, in ULPI PHY. **Value** **Description** 0x0 PHY drives VBUS using internal charge pump 0x1 PHY drives VBUS using external supply	RW	0x0

Bit	Name	Description	Access	Reset
19	ulpiclksusm	Mode:Host and Device. This bit sets the ClockSuspendM bit in the Interface Control register on the ULPI PHY. This bit applies only in serial or carkit modes. **Value** **Description** 0x0 PHY powers down internal clock during suspend 0x1 PHY does not power down internal clock	RW	0x0
18	ulpiautores	Mode:Host and Device. This bit sets the AutoResume bit in the Interface Control register on the ULPI PHY. **Value** **Description** 0x0 PHY does not use AutoResume feature 0x1 PHY uses AutoResume feature	RW	0x0
13:10	usbtrdtim	Mode: Device only. Sets the turnaround time in PHY clocks. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). The value is calculated for the minimum AHB frequency of 30 MHz. USB turnaround time is critical for certification where long cables and 5-Hubs are used, so If you need the AHB to run at less than 30 MHz, and If USB turnaround time is not critical, these bits can be programmed to a larger value. **Value** **Description** 0x9 MAC interface is 8-bit UTMI+.	RW	0x5
9	hnpcap	Mode:Host and Device. The application uses this bit to control the otg core's HNP capabilities. **Value** **Description** 0x0 HNP capability is not enabled. 0x1 HNP capability is enabled	RW	0x0

Bit	Name	Description	Access	Reset
8	srpcap	Mode:Host and Device. The application uses this bit to control the otg core SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. This bit is writable only If an SRP mode was specified for Mode of Operation in coreConsultant (parameter OTG_MODE). Otherwise, reads Return 0. **Value** **Description** 0x0 SRP capability is not enabled 0x1 SRP capability is enabled	RW	0x0
7	ddrsel	Mode:Host and Device. The application uses this bit to select a Single Data Rate (SDR) ULPI interface. DDR is not supported. **Value** **Description** 0x0 Single Data Rate ULPI Interfacewith 8-bit-wide data bus 0x1 Reserved	RW	0x0
6	physel	Mode:Host and Device. The application uses USB 2.0. **Value** **Description** 0x0 USB 2.0 high-speed ULPI	RO	0x0
5	fsintf	Mode:Host and Device. The application can Set this bit to select between the 3- and 6-pin interfaces, and access is Read and Write. **Value** **Description** 0x0 6-pin unidirectional full-speed serial interface 0x1 3-pin bidirectional full-speed serial interface	RO	0x0
4	ulpi_utmi_sel	Mode:Host and Device. The application uses ULPI Only in 8bit mode. **Value** **Description** 0x0 ULPI PHY	RO	0x1

Bit	Name	Description	Access	Reset
3	phyif	Mode:Host and Device. This application uses a ULPI interface only. Hence only 8-bit setting is relevant. This setting should not matter since UTMI is not enabled. **Value** **Description** 0x0 PHY 8bit Mode	RO	0x0
2:0	toutcal	Mode:Host and Device. The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: -One 30-MHz PHY clock = 16 bit times -One 60-MHz PHY clock = 8 bit times Full-speed operation: -One 30-MHz PHY clock = 0.4 bit times -One 60-MHz PHY clock = 0.2 bit times -One 48-MHz PHY clock = 0.25 bit times	RW	0x0

grstctl

The application uses this register to reset various hardware features inside the core

Module Instance	Base Address	Register Address

grstctl Fields

Bit	Name	Description	Access	Reset
31	ahbidle	Mode:Host and Device. Indicates that the AHB Master State Machine is in the IDLE condition. **Value** **Description** 0x0 Not Idle 0x1 AHB Master Idle	RO	0x1
30	dmareq	Mode:Host and Device. Indicates that the DMA request is in progress. Used for debug. **Value** **Description** 0x0 No DMA request 0x1 DMA request is in progress	RO	0x0

Bit	Name	Description	Access	Reset
10:6	txfnum	Mode:Host and Device. This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit. **Value** — **Description** 0x0 - Non-periodic TxFIFO flush in Host mode - Non-periodic TxFIFO flush in device mode when in shared FIFO operation 0x1 - Periodic TxFIFO flush in Host mode - Periodic TxFIFO 1 flush in Device mode when in sharedFIFO operation 0x2 - Periodic TxFIFO 2 flush in Device mode when in sharedFIFO operation- TXFIFO 2 flush in device mode when in dedicated FIFO mode 0xf - Periodic TxFIFO 15 flush in Device mode when in shared FIFO operation - TXFIFO 15 flush in device mode when in dedicated FIFO mode 0x10 Flush all the transmit FIFOs in device or host mode.	RW	0x0
5	txfflsh	Mode:Host and Device. This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is notreading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writinganything to the FIFO. Flushing is normally recommended when FIFOs are reconfig-ured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk. **Value** — **Description** 0x0 No Flush 0x1 selectively flushes a single or all transmit FIFOs	RO	0x0

Bit	Name	Description	Access	Reset
4	rxfflsh	Mode:Host and Device. The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear. **Value** **Description** 0x0 no flush the entire RxFIFO 0x1 flush the entire RxFIFO	RO	0x0
2	frmcntrrst	Mode:Host only. The application writes this bit to reset the (micro)frame number counter inside the core. When the (micro)frame counter is reset, the subsequent SOF sent out by the core has a (micro) frame number of 0. When application writes 1 to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles. **Value** **Description** 0x0 No reset 0x1 Host Frame Counter Reset	RO	0x0

Bit	Name	Description	Access	Reset
0	csftrst	Mode:Host and Device. Resets the hclk and phy_ clock domains as follows:Clears the interrupts and all the CSR registers except the following register bits: - PCGCCTL.RstPdwnModule - PCGCCTL.GateHclk - PCGCCTL.PwrClmp - PCGCCTL.StopPPhyLPwrClkSelclk - GUSBCFG.PhyLPwrClkSel - GUSBCFG.DDRSel - GUSBCFG.PHYSel - GUSBCFG.FSIntf - GUSBCFG.ULPI_UTMI_Sel - GUSBCFG.PHYIf - HCFG.FSLSPclkSel - DCFG.DevSpd - GGPIO - GPWRDN - GADPCTL All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. Any transactions on the AHB Master are terminated as soonas possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation. **Value** **Description** 0x0 No reset 0x1 Resets hclk and phy_clock domains	RO	0x0

gintsts

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared

automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintsts Fields

Bit	Name	Description	Access	Reset
31	wkupint	Mode:Host and Device. Wakeup Interrupt during Suspend(L2) or LPM(L1) state. -During Suspend(L2): - Device Mode - This interrupt is asserted only when Host Initiated Resume is detected on USB. - Host Mode - This interrupt is asserted only when Device Initiated Remote Wakeup is detected on USB - During LPM(L1):- - Device Mode - This interrupt is asserted for either Host Initiated Resume or Device Initiated Remote Wakeup on USB. - Host Mode - This interrupt is asserted for either Host Initiated Resume or Device Initiated Remote Wakeup on USB. **Value** **Description** 0x0 Not active 0x1 Resume Remote Wakeup Detected Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
30	sessreqint	Mode:Host and Device. In Host mode, this interrupt is asserted when a session request is detected from the device. In Host mode, this interrupt is asserted when a session request is detected from the device. In Device mode, this interrupt is asserted when the utmisrp_bvalid signal goes high. This bit can be set only by the core and the application should write 1 to clear. **Value** **Description** 0x0 Not active 0x1 Session Request New Session Detected Interrupt	RO	0x0
29	disconnint	Mode:Host only. Asserted when a device disconnect is detected. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 Not active 0x1 Disconnect Detected Interrupt	RO	0x0
28	ConIDStsChng	Mode:Host and Device. The core sets this bit when there is a change in connector ID status. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 Not Active 0x1 Connector ID Status Change	RO	0x1
26	ptxfemp	Mode:Host only. This interrupt is asserted when the Periodic Transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the Periodic Request Queue. The half or completely empty status is determined by the Periodic TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.PTxFEmpLvl). **Value** **Description** 0x0 Not active 0x1 Periodic TxFIFO Empty	RO	0x1

Bit	Name	Description	Access	Reset
25	hchint	Mode:Host only. The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the Host All Channels Interrupt (HAINT) register to determine the exact number of the channel on which the interrupt occurred, and Then read the corresponding Host Channel-n Interrupt (HCINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the HCINTn register to clear this bit. **Value** **Description** 0x0 Not active 0x1 Host Channels Interrupt	RO	0x0
24	prtint	Mode:Host only. The core sets this bit to indicate a change in port status of one of the otg core ports in Host mode. The application must read the Host Port Control and Status (HPRT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host PC Control and Status register to clear this bit. **Value** **Description** 0x0 0x1 Host Port Interrupt	RO	0x0
23	resetdet	Mode: Device only. In Device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in Suspend. In Host mode, this interrupt is not asserted. **Value** **Description** 0x0 Not active 0x1 Reset detected Interrup	RO	0x0

Bit	Name	Description	Access	Reset
22	fetsusp	Mode: Device only. This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or Request Queue space. This interrupt is used by the application for an endpoint mismatch algorithm. for example, after detecting an endpoint mismatch, the application: - Sets a Global non-periodic IN NAK handshake - Disables In endpoints - Flushes the FIFO - Determines the token sequence from the IN Token Sequence Learning Queue - Re-enables the endpoints - Clears the Global non-periodic IN NAK handshake If the Global non-periodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an IN token received when FIFO empty interrupt. The OTG Then sends the host a NAK response. To avoid this scenario, the application can check the GINTSTS.FetSusp interrupt, which ensures that the FIFO is full before clearing a Global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a Global IN NAKhandshake. **Value** **Description** 0x0 Not active 0x1 Data Fetch Suspended	RO	0x0
21	incomplp	Mode: Device only. In Host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending which arescheduled for the current microframe. Incomplete Isochronous OUT Transfer (incompISOOUT) The Device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. This bit can be set only by the core and the application should write 1 to clear it **Value** **Description** 0x0 Not active 0x1 Incomplete Periodic Transfer	RO	0x0

Bit	Name	Description	Access	Reset
20	incompisoin	Mode: Device only. The core sets this interrupt to indicate that there is at least isochronous IN endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. This interrupt is not asserted in Scatter/ Gather DMA mode. **Value** **Description** 0x0 Not active 0x1 Incomplete Isochronous IN Transfer	RO	0x0
19	oepint	Mode: Device only. The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the OUT endpoint on which the interrupt occurred, and Then read the corresponding Device OUT Endpoint-n Interrupt (DOEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DOEPINTn register to clear this bit. **Value** **Description** 0x0 Not active 0x1 OUT Endpoints Interrupt	RO	0x0
18	iepint	Mode: Device only. The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the IN endpoint on Device IN Endpoint-n Interrupt (DIEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DIEPINTn register to clear this bit. **Value** **Description** 0x0 Not active 0x1 IN Endpoints Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
17	epmis	Mode: Device only. This interrupt is valid only in shared FIFO operation. Indicates that an IN token has been received for a non-periodic endpoint, but the data for another endpoint is present in the top of the Non-periodic Transmit FIFO and the IN endpoint mismatch count programmed by the application has expired. **Value** **Description** 0x0 Not active 0x1 Endpoint Mismatch Interrup	RO	0x0
14	isooutdrop	Mode: Device only. The core sets this bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint. **Value** **Description** 0x0 Not active 0x1 Isochronous OUT Packet Dropped Interrup	RO	0x0
13	enumdone	Mode: Device only. The core sets this bit to indicate that speed enumeration is complete. The application must read the Device Status register to obtain the enumerated speed. **Value** **Description** 0x0 Not active 0x1 Enumeration Done	RO	0x0
12	usbrst	Mode: Device only. The core sets this bit to indicate that a reset is detected on the USB. **Value** **Description** 0x0 Not active 0x1 USB Reset	RO	0x0

Bit	Name	Description	Access	Reset
11	usbsusp	Mode: Device only. The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the phy_line_state_i signal for an extended period of time. **Value** **Description** 0x0 Not Active 0x1 USB Suspend	RO	0x0
10	erlysusp	Mode: Device only. The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms. **Value** **Description** 0x0 No Idle 0x1 Idle state detecetd	RO	0x0
7	goutnakeff	Mode: Device only. Indicates that the Set Global OUT NAK bit in the Device Control register (DCTL.SGOUTNak), Set by the application, has taken effect in the core. This bit can be cleared by writing the Clear Global OUT NAK bit in the Device Control register (DCTL.CGOUTNak). **Value** **Description** 0x0 No Active 0x1 Global OUT NAK Effective	RO	0x0
6	ginnakeff	Mode: Device only. Indicates that the Set Global Non-periodic IN NAK bit in the Device Control register (DCTL.SGNPInNak), Set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit Set by the application. This bit can be cleared by clearing the Clear Global Non-periodic IN NAK bit in the Device Control register (DCTL.CGNPInNak). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit. **Value** **Description** 0x0 Not active 0x1 Set Global Non-periodic IN NAK bi	RO	0x0

Bit	Name	Description	Access	Reset
4	rxflvl	Mode: Host and Device. Indicates that there is at least one packet pending to be read from the RxFIFO. **Value** **Description** 0x0 Not Active 0x1 Rx Fifo Non Empty	RO	0x0
3	sof	Mode: Host and Device. In Host mode, the core sets this bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In Device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. This bit can be set only by the core and the application should write 1 to clear it. This register may return 1 if read immediately after power on reset. If the register bit reads 1 immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit. **Value** **Description** 0x0 No sof 0x1 Start of Frame	RO	0x0
2	otgint	Mode: Host and Device. The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the GOTGINT register to clear this bit. **Value** **Description** 0x0 No Interrupt 0x1 OTG Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	modemis	Mode: Host and Device. The core sets this bit when the application is trying to access: -A Host mode register, when the core is operating in Device mode. -A Device mode register, when the core is operating in Host mode. The register access is completed on the AHB with an OKAYresponse, but is ignored by the core internally and does not affect the operation of the core. This bit can be set only by the core and the application should write 1 to clearit **Value** **Description** 0x0 No Mode Mismatch Interrupt 0x1 Mode Mismatch Interrupt	RO	0x0
0	curmod	Mode: Host and Device. Indicates the current mode. **Value** **Description** 0x0 Device mode 0x1 Host mode	RO	0x0

gintmsk

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsr Fields

Bit	Name	Description	Access	Reset
20:17	pktsts	Mode: Host only. Others: Reserved. Indicates the status of the received packet **Value** **Description** 0x2 IN data packet received 0x3 IN transfer completed (triggers an interrupt 0x5 Data toggle error (triggers an interrupt) 0x7 Channel halted (triggers an interrupt)	RO	0x0
16:15	dpid	Indicates the Data PID of the received packet. **Value** **Description** 0x0 DATA0 0x2 DATA1 0x1 DATA2 0x3 MDATA	RO	0x0
14:4	bcnt	Indicates the byte count of the received data packet.	RO	0x0
3:0	chnum	Indicates the endpoint number to which the current received packet belongs.	RO	0x0

grxstsp

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register'ss reset value before configuring the core because the read value is "X" in the simulation.

gpvndctl

The application can use this register to access PHY registers. for a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access

Module Instance	Base Address	Register Address

gpvndctl Fields

Bit	Name	Description	Access	Reset
31	disulpidrvr	The application sets this bit when it has finished processing the ULPI Carkit Interrupt (GINTSTS.ULPICKINT). When Set, the otg core disables drivers for output signals and masks input signal for the ULPI interface. otg clears this bit before enabling the ULPI interface. **Value** — **Description** 0x0 — ULPI ouput signals 0x1 — Disable ULPI ouput signals	RO	0x0
27	vstsdone	The core sets this bit when the vendor control access isdone. This bit is cleared by the core when the application sets the New Register Request bit (bit 25). **Value** — **Description** 0x0 — VStatus Done inactive 0x1 — VStatus Done active	RO	0x0

Bit	Name	Description	Access	Reset
26	vstsbsy	The core sets this bit when the vendor control access is in progress and clears this bit when done. **Value** **Description** 0x0 VStatus Busy inactive 0x1 VStatus Busy active	RO	0x0
25	newregreq	The application sets this bit for a new vendor controlaccess. **Value** **Description** 0x0 New Register Request not active 0x1 New Register Request active	RO	0x0
22	regwr	Set this bit for register writes, and clear it for register reads. **Value** **Description** 0x0 Register Read 0x1 Register Write	RW	0x0
21:16	regaddr	The 6-bit PHY register address for immediate PHY Register Set access. Set to 0x2F for Extended PHY Register Set access.	RW	0x0
15:8	vctrl	UTMI+ Vendor Control Register Address (VCtrl): The 4-bit register address a vendor defined 4-bit parallel output bus. Bits 11:8 of this field are placed on utmi_vcontrol[3:0]. ULPI Extended Register Address (ExtRegAddr): The 6-bit PHY extended register address.	RW	0x0
7:0	regdata	Contains the write data for register write. Read data for register read, valid when VStatus Done is Set.	RW	0x0

ggpio

The application can use this register for general purpose input/output ports or for debugging.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
31	dma	Enable descriptor based scatter/gather DMA. When enabled, DMA operations will be serviced with descriptor based scatter/gather DMA **Value** **Description** 0x1 Dynamic configuration	RO	0x1
30	dma_configuration	Selects bewteen scatter and nonscatter configuration **Value** **Description** 0x0 Non-Scatter/Gather DMA configuration 0x1 Scatter/Gather DMA configuration	RO	0x1

Bit	Name	Description	Access	Reset
29:26	ineps	Number of Device Mode IN Endpoints Including Control. **Value** — **Description** 0x0 — In Endpoint 1 0x1 — In Endpoint 2 0x2 — In Endpoint 3 0x3 — In Endpoint 4 0x4 — In Endpoint 5 0x5 — In Endpoint 6 0x6 — In Endpoint 7 0x7 — In Endpoint 8 0x8 — In Endpoint 9 0x9 — In Endpoint 10 0xa — In Endpoint 11 0xb — In Endpoint 12 0xc — In Endpoint 13 0xd — In Endpoint 14 0xe — In Endpoint 15 0xf — In Endpoint 16	RO	0xF
25	dedfifomode	Specifies whether Dedicated Transmit FIFOs should be enabled in device mode. **Value** — **Description** 0x1 — Dedicated Transmit FIFO Operation enabled	RO	0x1
24	sessendfltr	Specifies whether to add a filter on the session_end input from the PHY. **Value** — **Description** 0x0 — No filter	RO	0x0
23	bvalidfltr	Specifies whether to add a filter on the b_valid input from the PHY. **Value** — **Description** 0x0 — No Filter	RO	0x0

Bit	Name	Description	Access	Reset
22	avalidfltr	Specifies whether to add a filter on the b_valid input from the PHY. **Value** **Description** 0x0 No filter	RO	0x0
21	vbusvalidfltr	Vbus Valid Filter Enabled (VBusValidFltr) 0: No filter 1: Filter(coreConsultant parameter: OTG_EN_VBUSVALID_FILTER) **Value** **Description** 0x0 Vbus Valid Filter Disabled	RO	0x0
20	iddgfltr	Specifies whether to add a filter on the iddig input from the PHY. This is not relevant since we only support ULPI and there is no iddig pin exposed to I/O pads. **Value** **Description** 0x0 Iddig Filter Disabled	RO	0x0

Bit	Name	Description	Access	Reset
19:16	numctleps	Specifies the number of Device mode control endpoints in addition to control endpoint 0, which is always present. Range: 0-15. **Value** — **Description** 0x0 — End point 0 0x1 — End point 1 0x2 — End point 2 0x3 — End point 3 0x4 — End point 4 0x5 — End point 5 0x6 — End point 6 0x7 — End point 7 0x8 — End point 8 0x9 — End point 9 0xa — End point 10 0xb — End point 11 0xc — End point 12 0xd — End point 13 0xe — End point 14 0xf — End point 15	RO	0xF
15:14	phydatawidth	Uses a ULPI interface only. Hence only 8-bit setting is relevant. This setting should not matter since UTMI is not enabled.	RO	0x0
6	hibernation	Enables power saving mode hibernation. **Value** — **Description** 0x0 — Hibernation feature disabled	RO	0x0
5	ahbfreq	When the AHB frequency is less than 60 MHz, 4-deep clock-domain crossing sink and source buffers are instantiated between the MAC and the Packet FIFO Controller (PFC); otherwise, two-deep buffers are sufficient. **Value** — **Description** 0x1 — Minimum AHB Frequency Less Than 60 MH	RO	0x1

Bit	Name	Description	Access	Reset
4	partialpwrdn	Specifies whether to enable power optimization. Value: 0x0 — Description: Partial Power Down disabled	RO	0x0
3:0	numdevperioeps	The maximum number of device IN operations is 16 active at any time including endpoint 0, which is always present. This parameter determines the number of device mode Tx FIFOs to be instantiated.	RO	0x0

gdfifocfg

Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB0005C

Host Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Host mode.

Offset: 0x400

hcfg on page 18-118
Host Mode control. This register must be programmed every time the core changes to Host mode

hfir on page 18-121
This register stores the frame interval information for the current speed to which the otg core has enumerated

hfnum on page 18-122
This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue

hptxsts on page 18-123
This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue.

haint on page 18-125
When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

haintmsk on page 18-126
The Host All Channel Interrupt Mask register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

hflbaddr on page 18-127
This Register is valid only for Host mode Scatter-Gather DMA. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.

hprt on page 18-127
This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port.The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. for the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt

hcchar0 on page 18-132
Channel_number: 0.

hcsplt0 on page 18-135
Channel_number 0

hcint0 on page 18-137
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk0 on page 18-141
This register reflects the mask for each channel status described in the previous section.

hctsiz0 on page 18-142
Buffer DMA Mode

hcdma0 on page 18-144
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab0 on page 18-145
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar1 on page 18-146
Host Channel 1 Characteristics Register

hcsplt1 on page 18-149
Channel_number 1

hcint1 on page 18-151
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk1 on page 18-155
This register reflects the mask for each channel status described in the previous section.

hctsiz1 on page 18-156
Buffer DMA Mode

hcdma1 on page 18-158
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab1 on page 18-159
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar2 on page 18-160
Host Channel 2 Characteristics Register

hcsplt2 on page 18-163
Channel_number 2

hcint2 on page 18-165
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk2 on page 18-169
This register reflects the mask for each channel status described in the previous section.

hctsiz2 on page 18-170
Buffer DMA Mode.

hcdma2 on page 18-172
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab2 on page 18-173
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar3 on page 18-174
Channel_number: 3.

hcsplt3 on page 18-177
Channel_number 3

hcint3 on page 18-179
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk3 on page 18-183
This register reflects the mask for each channel status described in the previous section.

hctsiz3 on page 18-184
Buffer DMA Mode

hcdma3 on page 18-186
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab3 on page 18-187
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar4 on page 18-188
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcsplt4 on page 18-189
Channel_number 4

hcint4 on page 18-190
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk4 on page 18-194
This register reflects the mask for Channel 4 interrupt status bits.

hctsiz4 on page 18-196
Buffer DMA Mode Channel 4

hcdma4 on page 18-197
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab4 on page 18-198
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar5 on page 18-199
Channel_number: 5.

hcsplt5 on page 18-203
Channel_number 5

hcint5 on page 18-205

hcfg Fields

Bit	Name	Description	Access	Reset
31	modechtimen	This bit is used to enable or disable the host core to wait for 200 PHY clock cycles at the end of Resume to change the opmode signal to the PHY to 00 after Suspend or LPM. **Value** **Description** 0x0 The Host core waits for either 200 PHY clock cycles or a linestate of SE0 at the end of resume to change the opmode from 0x2 to 0x0 0x1 The Host core waits only for a linestate of SE0 at the end of resume to change the opmode from 0x2 to 0x0	RW	0x0
26	perschedena	Applicable in Scatter/Gather DMA mode only. Enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. As soon as this bit is set, the core will get ready to start scheduling periodic channels. In non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 Disables periodic scheduling within the core 0x1 Enables periodic scheduling within the core	RW	0x0
25:24	frlisten	The value in the register specifies the number of entries in the Frame list. This field is valid only in Scatter/Gather DMA mode. **Value** **Description** 0x0 Reserved 0x1 8 Entries 0x2 16 Entries 0x3 32 Entries	RW	0x0

Bit	Name	Description	Access	Reset
23	descdma	The application can set this bit during initialization to enable the Scatter/Gather DMA operation. This bit must be modified only once after a reset. The following combinations are available for programming: GAHBCFG.DMAEn=0,HCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0,HCFG.DescDMA=1 => InvalidGAHBCFG.DMAEn=1,HCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1,HCFG.DescDMA=1 => Scatter/Gather DMA mode **Value** **Description** 0x0 No Scatter/Gather DMA 0x1 Scatter/Gather DMA selected	RW	0x0
15:8	resvalid	This field is effective only when HCFG.Ena32KHzS is set. It will control the resume period when the core resumes from suspend. The core counts for ResValid number of clock cycles to detect a valid resume when this is set.	RW	0x2
7	ena32khzs	This bit can only be set if the USB 1.1 Full-Speed Serial Transceiver Interface has been selected. If USB 1.1 Full-Speed Serial Transceiver Interface has not been selected, this bit must be zero. When the USB 1.1 Full-Speed Serial Transceiver Interface is chosen and this bit is set, the core expects the 48-MHz PHY clock to be switched to 32 KHz during a suspend. **Value** **Description** 0x0 USB 1.1 Full-Speed Not Selected 0x1 USB 1.1 Full-Speed Serial Transceiver Interface selected	RW	0x0
2	fslssupp	The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as a FS host, even If the connected device supports HS traffic. Do not make changes to this field after initial programming. **Value** **Description** 0x0 HS/FS/LS, based on the maximum speed supported by the connected device 0x1 FS/LS-only, even if the connected device can support HS	RW	0x0

Bit	Name	Description	Access	Reset
1:0	fslspclksel	When the core is in FS Host mode. The internal PHY clock is running at 30/60 MHZ for ULPI PHY Interfaces. The internal PHY clock is running at 48MHZ for 1.1 FS transceiver Interface When the core is in LS Host mode, the internal PHY clock is running at 30/60 MHZ for ULPI PHY Interfaces. The internal PHY clock is running at 6 MHZ and the external clock is running at 48MHZ. When you select a 6 MHz clock during LS Mode, you must do a soft reset for 1.1 FS transceiver Interface. * When Core in FS mode, the internal and external clocks have the same frequency. * When Core in LS mode, - If fslspclksel is 30/60 Mhz internal and external clocks have the same frequency. - If fslspclksel is 6Mhz the internal clock is divided by eight of external 48 MHz clock (utmifs_clk). **Value** **Description** 0x0 PHY clock is running at 30/60 MHz 0x1 PHY clock is running at 48 MHz 0x2 PHY clock is running at 6 MHz	RW	0x0

hfir

This register stores the frame interval information for the current speed to which the otg core has enumerated

haint

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt).

There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

Module Instance	Base Address	Register Address

31:0	hflbaddr	This Register is valid only for Host mode Scatter-Gather DMA mode. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.	RW	0x0

hprt

This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port.The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. for the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt

hprt Fields

Bit	Name	Description	Access	Reset
18:17	prtspd	Indicates the speed of the device attached to this port. **Value** — **Description** 0x0 — High speed 0x1 — Full speed 0x2 — Low speed 0x3 — Reserved	RO	0x0
16:13	prttstctl	The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port. **Value** — **Description** 0x0 — Test mode disabled 0x1 — Test_J mode 0x2 — Test_K mode 0x3 — Test_SE0_NAK mode 0x4 — Test_Packet mode 0x5 — Test_force_Enable	RW	0x0

Bit	Name	Description	Access	Reset
12	prtpwr	The application uses this field to control power to this port, and the core can clear this bit on an over current condition. **Value** — **Description** 0x0 — Power off 0x1 — Power on	RW	0x0
11:10	prtlnsts	Indicates the current logic level USB data lines. Bit [10]: Logic level of D+ Bit [11]: Logic level of D- **Value** — **Description** 0x1 — Logic level of D+ 0x2 — Logic level of D-	RO	0x0
8	prtrst	When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete. The application must leave this bit Set for at least a minimum duration mentioned below to start a reset on the port. The application can leave it Set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by theUSB standard. This bit is cleared by the core even if there is no device connected to the Host. High speed: 50 ms Full speed/Low speed: 10 ms **Value** — **Description** 0x0 — Port not in reset 0x1 — Port in reset	RW	0x0

Bit	Name	Description	Access	Reset
7	prtsusp	The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is Set. To stop the PHY clock, the application must Set the Port Clock Stop bit, which asserts the suspend input pin of the PHY. The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the Port Reset bit or Port Resume bit in this register or the Resume/Remote Wakeup Detected Interrupt bit or Disconnect Detected Interrupt bit in the Core Interrupt register (GINTSTS.WkUpInt or GINTSTS.DisconnInt, respectively). This bit is cleared by the core even if there is no device connected to the Host. **Value** — **Description** 0x0 — Port not in Suspend mode 0x1 — Port in Suspend mode	RO	0x0
6	prtres	The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the Port Resume/Remote Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.WkUpInt), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently drivingresume signaling. When LPM is enabled and the core is in the L1 (Sleep) state, setting this bit results in the following behavior: The core continues to drive the resume signal until a predetermined time specified in the GLPMCFG.HIRD_Thres[3:0] field. If the core detects a USB remote wakeup sequence, as indicated by the Port L1 Resume/Remote L1 Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.L1WkUpInt), the core starts driving resume signaling without application intervention and clears this bit at the end of the resume. The read value of this bit indicates whether the core is currently driving resume signaling. **Value** — **Description** 0x0 — No resume driven 0x1 — Resume driven	RW	0x0

Bit	Name	Description	Access	Reset
5	prtovrcurrchng	The core sets this bit when the status of the PortOvercurrent Active bit (bit 4) in this register changes.This bit can be set only by the core and the application should write 1 to clear it **Value** **Description** 0x0 Status of port overcurrent no change 0x1 Status of port overcurrent changed	RO	0x0
4	prtovrcurract	Indicates the overcurrent condition of the port. 0x0: No overcurrent condition 0x1: Overcurrent condition **Value** **Description** 0x0 No overcurrent condition 0x1 Overcurrent condition	RO	0x0
3	prtenchng	The core sets this bit when the status of the Port Enable bit [2] of this register changes. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 Port Enable bit 2 no change 0x1 Port Enable bit 2 changed	RO	0x0
2	prtena	A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot Set this bit by a register write. It can only clear it to disable the port by writing 1. This bit does not trigger any interrupt to the application. **Value** **Description** 0x0 Port disabled 0x1 Port enabled	RO	0x0

Bit	Name	Description	Access	Reset
1	PrtConnDet	The core sets this bit when a device connection is detected to trigger an interrupt to the application using the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). This bit can be set only by the core and the application should write 1 to clear it.The application must write a 1 to this bit to clear the interrupt. **Value** **Description** 0x0 Device connection detected 0x1 No device connection detected	RO	0x0
0	prtconnsts	Defines whether port is attached. **Value** **Description** 0x0 No device is attached to the port 0x1 A device is attached to the port	RO	0x0

hcchar0 Fields

Bit	Name	Description	Access	Reset
31	chena	When Scatter/Gather mode is disabled. This field is set by the application and cleared by the OTG host. **Value** **Description** 0x0 Indicates that the descriptor structure is not yet ready 0x1 Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor	RO	0x0
30	chdis	The application sets this bit to stop transmitting/ receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel Disabled interrupt before treating the channel as disabled. **Value** **Description** 0x0 No activity 0x1 Stop transmitting/receiving data	RO	0x0
28:22	devaddr	This field selects the specific device serving as the data source or sink.	RW	0x0
21:20	ec	When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (0), this field indicates to the host the number of transactions that must be executed per microframe for this periodic endpoint. for non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched for this channel before the internal DMA engine changes arbitration. When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed for a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 Reserved This field yields undefined results 0x1 1 transaction 0x2 2 transactions to be issued for this endpoint per microframe 0x3 3 transactions to be issued for this endpoint per microframe	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Indicates the transfer type selected. Value: Description 0x0: Control 0x1: Isochronous 0x2: Bulk 0x3: Interrupt	RW	0x0
17	lspddev	This field is Set by the application to indicate that this channel is communicating to a low-speed device. The application must program this bit when a low speed device is connected to the host through an FS HUB. The HS OTG Host core uses this field to drive the XCVR_SELECT signal to 0x3 while communicating to the LS Device through the FS hub. In a peer to peer setup, the HS OTG Host core ignores this bit even if it is set by the application software. Value: Description 0x0: Communicating with non lowspeed 0x1: Communicating with lowspeed	RW	0x0
15	epdir	Indicates whether the transaction is IN or OUT. Value: Description 0x0: OUT 0x1: IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0x0 — End point 0 0x1 — End point 1 0x2 — End point 2 0x3 — End point 3 0x4 — End point 4 0x5 — End point 5 0x6 — End point 6 0x7 — End point 7 0x8 — End point 8 0x9 — End point 9 0xa — End point 10 0xb — End point 11 0xc — End point 12 0xd — End point 13 0xe — End point 14 0xf — End point 15	RW	0x0
10:0	mps	Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint0

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

31:0	hcdma0	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcint1

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint1 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk1

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint2 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk2

hcdma2 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma2	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab2

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint3

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma3

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma3 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma3	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab3

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint4

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk5

This register reflects the mask for each channel status described in the previous section.

hcdma5 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma5	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab5

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

6:0	prtaddr	This field is the port number of the recipient transac-tiontranslator.	RW	0x0

hcint6

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma6 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma6	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab6

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint7

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint7 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Descriptor rollover interrupt 0x1 — Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk7

This register reflects the mask for each channel status described in the previous section.

hctsiz7 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma7

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint8 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk8

This register reflects the mask for each channel status described in the previous section.

hctsiz8 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma8

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma8 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma8	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab8

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint9

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma9 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma9	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab9

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint10

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Descriptor rollover interrupt 0x1 — Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

Bit	Name	Description	Access	Reset
31	spltena	The application sets this field to indicate that this channel is enabled to perform split transactions. **Value** **Description** 0x0 Split not enabled 0x1 Split enabled	RW	0x0
16	compsplt	The application sets this field to request the OTG host to perform a complete split transaction. **Value** **Description** 0x0 No split transaction 0x1 Split transaction	RW	0x0
15:14	xactpos	This field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction. **Value** **Description** 0x0 Mid. This is the middle payload of this transaction (which is larger than 188 bytes) 0x1 End. This is the last payload of this transaction (which is larger than 188 bytes) 0x2 Begin. This is the first data payload of this transaction (which is larger than 188 bytes) 0x3 All. This is the entire data payload is of this transaction (which is less than or equal to 188 bytes)	RW	0x0
13:7	hubaddr	This field holds the device address of the transaction translator's hub.	RW	0x0

Bit	Name	Description	Access	Reset
6:0	prtaddr	This field is the port number of the recipient transac-tiontranslator.	RW	0x0

hcint11

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint11 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk11

hctsiz11 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma11

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma11 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma11	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab11

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdma12 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma12	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab12

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint13

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint14

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint14 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	datatglerr	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	frmovrun	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk14

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.	RW	0x0

hcdma14

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma14 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma14	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab14

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk15

This register reflects the mask for each channel status described in the previous section.

hctsiz15 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma15

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma15 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma15	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab15

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.	RW	0x0

Device Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Device mode.

Offset: 0x800

dcfg on page 18-370
This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

dctl on page 18-373

dsts on page 18-378
This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

diepmsk on page 18-380
This register works with each of the Device IN Endpoint Interrupt (DIEPINTn) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINTn register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

doepmsk on page 18-382
This register works with each of the Device OUT Endpoint Interrupt (DOEPINTn) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the DOEPINTn register can be masked by writing into the corresponding bit in this register. Status bits are masked by default

daint on page 18-384
When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. for a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

daintmsk on page 18-390
The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

dvbusdis on page 18-395
This register specifies the VBUS discharge time after VBUS pulsing during SRP.

dvbuspulse on page 18-395
This register specifies the VBUS pulsing time during SRP.

dthrctl on page 18-396
Thresholding is not supported in Slave mode and so this register must not be programmed in Slave mode. for threshold support, the AHB must be run at 60 MHz or higher.

diepempmsk on page 18-399
This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

diepctl0 on page 18-402
This register covers Device Control IN Endpoint 0.

diepint0 on page 18-405
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz0 on page 18-409
The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 on page 18-410
DMA Addressing.

dtxfsts0 on page 18-411
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab0 on page 18-411
Endpoint 16.

diepctl1 on page 18-412
Endpoint_number: 1

diepint1 on page 18-418
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz1 on page 18-422
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma1 on page 18-423
DMA Addressing.

dtxfsts1 on page 18-424
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab1 on page 18-425
DMA Buffer Address.

diepctl2 on page 18-425
Endpoint_number: 2

diepint2 on page 18-431
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz2 on page 18-435
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma2 on page 18-436

diepdmab14 on page 18-594
DMA Buffer Address.

diepctl15 on page 18-595
Endpoint_number: 15

diepint15 on page 18-600
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz15 on page 18-604
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dcfg Fields

Bit	Name	Description	Access	Reset
31:26	resvalid	This field is effective only when DCFG.Ena32KHzSusp is set. It will control the resume period when the core resumes from suspend. The core counts for ResValid number of clock cycles to detect a valid resume when this is set	RW	0x2

Bit	Name	Description	Access	Reset
25:24	perschintvl	PerSchIntvl must be programmed only for Scatter/Gather DMAmode. Description: This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25,50 or 75% of (micro)frame. When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data . When no periodic endpoints are active, Then the internal DMA engine services non-periodic endpoints, ignoring this field. After the specified time within a (micro)frame, the DMA switches to fetching for non-periodic endpoints. 2'b00: 25% of (micro)frame. 2'b01: 50% of (micro)frame. 2'b10: 75% of (micro)frame. 2'b11: Reserved.Reset: 2'b00Access: read-write **Value** — **Description** 0x0 — 25% of (micro)frame 0x1 — 50% of (micro)frame 0x2 — 75% of (micro)frame 0x3 — Reserved	RW	0x0
23	descdma	When the Scatter/Gather DMA option selected during configuration of the RTL, the application can Set this bit during initialization to enable the Scatter/Gather DMA operation. This bit must be modified only once after a reset.The following combinations are available for programming: GAHBCFG.DMAEn=0,DCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0,DCFG.DescDMA=1 => Invalid GAHBCFG.DMAEn=1,DCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1,DCFG.DescDMA=1 => Scatter/Gather DMA mode **Value** — **Description** 0x0 — Disable Scatter gather DMA 0x1 — Enable Scatter gather DMA	RW	0x0

Bit	Name	Description	Access	Reset
13	endevoutnak	This bit enables setting NAK for Bulk OUT endpoints after the transfer is completed for Device mode Descriptor DMA It is one time programmable after reset like any other DCFG register bits. **Value** **Description** 0x0 The core does not set NAK after Bulk OUT transfer complete 0x1 The core sets NAK after Bulk OUT transfer complete	RW	0x0
12:11	perfrint	Indicates the time within a (micro)frame at which the application must be notified using the End Of Periodic Frame Interrupt. This can be used to determine If all the isochronous traffic for that (micro)frame is complete. 0x0: 80% of the (micro) frame interval 0x1: 85% 0x2: 90% 0x3: 95% **Value** **Description** 0x0 80% of the (micro)frame interval 0x1 85% of the (micro)frame interval 0x2 90% of the (micro)frame interval 0x3 95% of the (micro)frame interval	RW	0x0
10:4	devaddr	The application must program this field after every SetAddress control command.	RW	0x0
3	ena32khzsusp	When the USB 1.1 Full-Speed Serial Transceiver Interface is chosen and this bit is set, the core expects the 48-MHz PHY clock to be switched to 32 KHz during a suspend. This bit can only be set if USB 1.1 Full-Speed Serial Transceiver Interface has been selected. If USB 1.1 Full-Speed Serial Transceiver Interface has not been selected, this bit must be zero. **Value** **Description** 0x0 USB 1.1 Full-Speed Serial Transceiver not selected 0x1 USB 1.1 Full-Speed Serial Transceiver Interface selected	RW	0x0

Bit	Name	Description	Access	Reset
2	nzstsouthshk	The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage. 1: Send a STALL handshake on a nonzero-length statusOUT transaction and do not send the received OUT packet tothe application. 0: Send the received OUT packet to the application (zerolengthor nonzero-length) and send a handshake based onthe NAK and STALL bits for the endpoint in the DeviceEndpoint Control register. **Value** **Description** 0x0 Send the received OUT packet to the application zerolength 0x1 Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application	RW	0x0
1:0	devspd	Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected. **Value** **Description** 0x0 High speed USB 2.0 PHY clock is 30 MHz or 60 MHz 0x1 Full speed USB 2.0 PHY clock is 30 MHz or 60 MHz 0x2 Low speed USB 1.1 transceiver clock is 6 MHz 0x3 Full speed USB 1.1 transceiver clock is 48 MHz	RW	0x0

dctl Fields

Bit	Name	Description	Access	Reset
16	nakonbble	Set NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received. **Value** **Description** 0x0 Disable NAK on Babble Error 0x1 NAK on Babble Error	RW	0x0

Bit	Name	Description	Access	Reset
15	ignrfrmnum	Do NOT program IgnrFrmNum bit to 1'b1 when the core is operating in threshold mode. When Scatter/Gather DMA mode is enabled this feature is not applicable to High Speed, High bandwidth transfers. When this bit is enabled, there must be only one packet per descriptor. In Scatter/Gather DMA mode, if this bit is enabled, the packets are not flushed when a ISOC IN token is received for an elapsed frame. When Scatter/Gather DMA mode is disabled, this field is used by the application to enable periodic transfer interrupt. The application can program periodic endpoint transfers for multiple (micro) frames. 0: periodic transfer interrupt feature is disabled, application needs to program transfers for periodic endpoints every (micro)frame 1: periodic transfer interrupt feature is enabled, application can program transfers for multiple (micro)frames for periodic endpoints. In non Scatter/Gather DMA mode the application will receive transfer complete interrupt after transfers for multiple (micro)frames are completed. **Value** — **Description** 0x0 — The core transmits the packets only in the frame number in which they are intended to be transmitted 0x1 — The core ignores the frame number, sending packets immediately as the packets are ready	RW	0x0
14:13	gmc	GMC must be programmed only once after initialization.Applicable only for Scatter/Gather DMA mode. This indicates the number of packets to be serviced for that end point before moving to the next end point. It is only for non-periodic end points. When Scatter/Gather DMA mode is disabled, this field isreserved. and reads 0. **Value** — **Description** 0x0 — Invalid 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0

Bit	Name	Description	Access	Reset
11	pwronprgdone	The application uses this bit to indicate that register-programming is completed after a wake-up from Power Downmode. **Value** **Description** 0x0 Power-On Programming not done 0x1 Power-On Programming Done	RW	0x0
10	cgoutnak	A write to this field clears the Global OUT NAK. **Value** **Description** 0x0 Disable Clear Global OUT NAK 0x1 Clear Global OUT NAK	WO	0x0
9	sgoutnak	A write to this field sets the Global OUT NAK.The application uses this bit to send a NAK handshake on all OUT endpoints. The application must Set the this bit only after making sure that the Global OUT NAK Effective bit in the Core Interrupt Register GINTSTS.GOUTNakEff) is cleared. **Value** **Description** 0x0 Disable Global OUT NAK 0x1 Global OUT NAK	WO	0x0
8	CGNPInNak	A write to this field clears the Global Non-periodic IN NAK. **Value** **Description** 0x0 Disable Global Non-periodic IN NAK 0x1 Clear Global Non-periodic IN NAK	WO	0x0

Bit	Name	Description	Access	Reset
7	sgnpinnak	A write to this field sets the Global Non-periodic IN NAK. The application uses this bit to send a NAK handshake on all nonperiodic IN endpoints. The core can also Set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must Set this bit only after making sure that the Global IN NAK Effective bit in the Core Interrupt Register (GINTSTS.GINNakEff) is cleared **Value** **Description** 0x0 Disable Global Non-periodic IN NAK 0x1 Global Non-periodic IN NAK	WO	0x0
6:4	tstctl	Others: Reserved. **Value** **Description** 0x0 Test mode disabled 0x1 Test_J mode 0x2 Test_K mode 0x3 Test_SE0_NAK mode 0x4 Test_Packet mode 0x5 Test_force_Enable	RW	0x0
3	goutnaksts	Reports NAK status. All isochronous OUT packets aredropped. **Value** **Description** 0x0 A handshake is sent based on the FIFO Status and the NAK and STALL bit settings. 0x1 No data is written to the RxFIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.	RO	0x0
2	gnpinnaksts	Defines IN NAK conditions. **Value** **Description** 0x0 A handshake is sent out based on the data availability in the transmit FIFO 0x1 A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.	RO	0x0

Bit	Name	Description	Access	Reset
1	sftdiscon	The application uses this bit to signal the otg core to do a soft disconnect. As long as this bit is Set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. There is a minimum duration for which the core must keep this bit set. When this bit is cleared after a soft disconnect, the core drives the phy_opmode_o signal on the ULPI, which generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.; **Value** **Description** 0x0 Normal operation 0x1 The core drives the phy_opmode_o signal on the ULPI	RW	0x0
0	rmtwkupsig	When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must Set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 115 ms after setting it. Remote Wakeup Signaling (RmtWkUpSig) When LPM is enabled, In L1 state the behavior of this bit is as follows: When the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the Sleep state. As specified in the LPM specification, the hardware will automatically clear this bit after a time of 50us (TL1DevDrvResume) after set by application. Application should not set this bit when GLPMCFG bRemoteWake from the previous LPM transaction was zero. **Value** **Description** 0x0 No exit suspend state 0x1 Exit Suspend State	RW	0x0

dsts

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

Module Instance	Base Address	Register Address

dsts Fields

Bit	Name	Description	Access	Reset
21:8	soffn	When the core is operating at high speed, this field contains a microframe number. When the core is operating at full or low speed, this field contains a Frame number.	RO	0x0
3	errticerr	The core sets this bit to report any erratic errors (phy_rxvalid_i/phy_rxvldh_i or phy_rxactive_i is asserted for at least 2 ms, due to PHY error) seen on the UTMI+ . Due to erratic errors, the otg core goes into Suspended state and an interrupt is generated to the application with Early Suspend bit of the Core Interrupt register (GINTSTS.ErlySusp). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover. **Value** — **Description** 0x0 — No Erratic Error 0x1 — Erratic Error	RO	0x0

Bit	Name	Description	Access	Reset
2:1	enumspd	Indicates the speed at which the otg core has come up after speed detection through a chirp sequence. **Value** — **Description** 0x0 — High speed (PHY clock is running at 30 or 60 MHz) 0x1 — Full speed (PHY clock is running at 30 or 60 MHz) 0x2 — Low speed (PHY clock is running at 6 MHz) 0x3 — Full speed (PHY clock is running at 48 MHz)	RO	0x1
0	suspsts	In Device mode, this bit is Set as long as a Suspend condition is detected on the USB. The core enters the Suspended state when there is no activity on the phy_line_state_i signal for an extended period of time. The core comes out of the suspend: -When there is any activity on the phy_line_state_i signal -When the application writes to the Remote Wakeup Signaling bit in the Device Control register (DCTL.RmtWkUpSig). **Value** — **Description** 0x0 — No suspend state 0x1 — Suspend state	RO	0x0

diepmsk

This register works with each of the Device IN Endpoint Interrupt (DIEPINTn) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINTn register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

daint

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). There is one interrupt bit

per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. for a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

dthrctl Fields

Bit	Name	Description	Access	Reset
27	arbprken	This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is Set to one, Then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By Default the parking is enabled. **Value** **Description** 0x0 Disable DMA arbiter parking 0x1 Enable DMA arbiter parking for IN endpoints	RW	0x1
25:17	rxthrlen	This field specifies Receive thresholding size in DWORDS.This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight DWORDS. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	RW	0x8
16	rxthren	When this bit is Set, the core enables thresholding in the receive direction. **Value** **Description** 0x0 Disable thresholding 0x1 Enable thresholding in the receive direction	RW	0x0

Bit	Name	Description	Access	Reset
12:11	ahbthrratio	These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements. **Value** — **Description** 0x0 — AHB threshold = MAC threshold 0x1 — AHB threshold = MAC threshold /2 0x2 — AHB threshold = MAC threshold /4 0x3 — AHB threshold = MAC threshold /	RW	0x0
10:2	txthrlen	This field specifies Transmit thresholding size in DWORDS. This also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length has to be at least eight DWORDS when the value of AHBThrRatio is 0. In case the AHBThrRatio is non zero the application needs to ensure that the AHB Threshold value does not go below the recommended eight DWORD. This field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	RW	0x8
1	isothren	When this bit is Set, the core enables thresholding for isochronous IN endpoints. **Value** — **Description** 0x0 — No thresholding 0x1 — Enables thresholding	RW	0x0

Bit	Name	Description	Access	Reset
0	nonisothren	When this bit is Set, the core enables thresholding for Non Isochronous IN endpoints. **Value** **Description** 0x0 No thresholding 0x1 Enable thresholding	RW	0x0

diepempmsk

This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

Bit	Name	Description	Access	Reset
31	epena	When Scatter/Gather DMA mode is enabled, for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. When Scatter/Gather DMA mode is disabled such as in bufferpointer based DMA mode this bit indicates that data is ready to be transmitted on the endpoint. The core clears this bit before setting the following interrupts on this endpoint: -Endpoint Disabled -Transfer Completed **Value** **Description** 0x0 No action 0x1 Endpoint Enabled	RO	0x0
30	epdis	The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled Interrupt. The application must Set this bit only If Endpoint Enable is already Set for this endpoint. **Value** **Description** 0x0 No action 0x1 Stop transmitting data on endpoint	RO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No action 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No action 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	for Shared FIFO operation, this value is always Set to 0, indicating that control IN endpoint 0 data is always written in the Non-Periodic Transmit FIFO. for Dedicated FIFO operation, this value is Set to the FIFO number that is assigned to IN Endpoint 0.	RW	0x0
21	stall	The application can only Set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Nonperiodic IN NAK, or Global OUT NAK is Set along with this bit, the STALL bit takes priority. **Value** **Description** 0x0 No Stall 0x1 Stall Handshake	RO	0x0
19:18	eptype	Hardcoded to 00 for control. **Value** **Description** 0x0 Endpoint Control 0	RO	0x0
17	naksts	When this bit is Set, either by the application or core, the core stops transmitting data, even If there is data available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
15	usbactep	This bit is always SET to 1, indicating that control endpoint 0 is always active in all configurations and interfaces. **Value** **Description** 0x1 Control endpoint is always active	RO	0x1

Bit	Name	Description	Access	Reset
1:0	mps	Applies to IN and OUT endpoints.The application must program this field with the maximum packet size for the current logical endpoint. Value: Description 0x0: 64 bytes 0x1: 32 bytes 0x2: 16 bytes 0x3: 8 bytes	RW	0x0

diepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint0 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma0	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint1 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz1 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl2 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint2 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz2 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma2 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma2	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

DTXFSTS2

diepctl3 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint3 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint4 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz4 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz5 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl6 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

diepint6 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. Value: 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. Value: 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

dieptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl7 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint7 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz7 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma7	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts7

13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz8 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint9 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl10 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint10 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz10 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint11 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma11 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma11	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts11

diepctl12 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma12	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts12

This register contains the free space information for the Device IN endpoint TxFIFO.

diepctl13 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint13 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz13 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint14 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz14 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz15

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz15 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

doepctl0 Fields

Bit	Name	Description	Access	Reset
31	epena	When Scatter/Gather DMA mode is enabled, for OUT endpoints this bit indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is disabled(such as for buffer-pointer based DMA mode)this bit indicates that the application has allocated the memory to start receiving data from the USB.The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed In DMA mode, this bit must be Set for the core to transfer SETUP data packets into memory. **Value** **Description** 0x0 No action 0x1 Endpoint Enabled	RO	0x0
30	epdis	The application cannot disable control OUT endpoint 0. **Value** **Description** 0x0 No Endpoint disable	RO	0x0

Bit	Name	Description	Access	Reset
27	snak	A write to this bit sets the NAK bit for the endpoint.Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. **Value** **Description** 0x0 No action 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No action 0x1 Clear NAK	WO	0x0
21	stall	The application can only Set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is Set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 No Stall 0x1 Stall Handshake	RO	0x0
20	snp	This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Snoop Mode disabled 0x1 Snoop Mode enabled	RW	0x0
19:18	eptype	Hardcoded to 0 for control. **Value** **Description** 0x0 Endpoint Control 0	RO	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit, the core stops receiving data, even If there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
15	usbactep	This bit is always Set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces. **Value** **Description** 0x1 USB Active Endpoint 0	RO	0x1
1:0	mps	The maximum packet size for control OUT endpoint 0 is thesame as what is programmed in control IN Endpoint 0. **Value** **Description** 0x0 64 bytes 0x1 32 bytes 0x2 16 bytes 0x3 8 bytes	RO	0x0

doepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint0 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0

Bit	Name	Description	Access	Reset
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0

Bit	Name	Description	Access	Reset
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

doepctl1 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. h 1'b0'b0: Even (micro)frame 1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz1 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** **Description** 0x0 DATA0 0x1 DATA2 or 1 packet 0x2 DATA1 or 2 packets 0x3 MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

DOEPCTL2 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint2 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint3 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doeptsiz3 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** — **Description** 0x0 — DATA0 0x1 — DATA2 or 1 packet 0x2 — DATA1 or 2 packets 0x3 — MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepdma3

DMA OUT Address.

doepctl4 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — Disable Snoop Mode 0x1 — Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

Doepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

Doepint4 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz4 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** **Description** 0x0 DATA0 0x1 DATA2 or 1 packet 0x2 DATA1 or 2 packets 0x3 MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepdma4

DMA OUT Address.

doepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma4	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab4

DMA Buffer Address.

doepctl5 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

doepint5 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl6 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

doepint6 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doepctl7 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint7 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0

Bit	Name	Description	Access	Reset
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl8 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint8 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doeptsiz8 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** — **Description** 0x0 — DATA0 0x1 — DATA2 or 1 packet 0x2 — DATA1 or 2 packets 0x3 — MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepdma8

DMA OUT Address.

doepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma8	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab8

doepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

doepint9 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doeptsiz9 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** **Description** 0x0 DATA0 0x1 DATA2 or 1 packet 0x2 DATA1 or 2 packets 0x3 MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepdma9

DMA OUT Address.

doepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma9	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl10 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint10 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl11 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — Disable Snoop Mode 0x1 — Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint11 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl12 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint12 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma12	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl13 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint13 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Module Instance	Base Address	Register Address

doepctl14 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint14 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz14 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** **Description** 0x0 DATA0 0x1 DATA2 or 1 packet 0x2 DATA1 or 2 packets 0x3 MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint15 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz15

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Power and Clock Gating Register Register Descriptions

There is a single register for power and clock gating. It is available in both Host and Device modes.

Offset: 0xe00

pcgcctl on page 18-797
This register is available in Host and Device modes. The application can use this register to control the core's power-down and clock gating features. Because the CSR module is turned off during power-down, this register is implemented in the AHB Slave BIU module.

pcgcctl

This register is available in Host and Device modes. The application can use this register to control the core's power-down and clock gating features. Because the CSR module is turned off during power-down, this register is implemented in the AHB Slave BIU module.

Module Instance	Base Address	Register Address

pcgcctl Fields

Bit	Name	Description	Access	Reset
7	l1suspended	Indicates that the PHY is in deep sleep when in L1 state. **Value** **Description** 0x0 Non Deep Sleep 0x1 Deep Sleep active	RO	0x0
6	physleep	Indicates that the PHY is in Sleep State. **Value** **Description** 0x0 Phy non-sleep 0x1 Phy sleep state	RO	0x0
3	rstpdwnmodule	This bit is valid only in Partial Power-Down mode. Theapplication sets this bit when the power is turned off. The application clears this bit after the power is turned on and the PHY clock is up. The R/W of all core registers are possible only when this bit is set to 1b0. **Value** **Description** 0x0 Power is turned on 0x1 Power is turned off	RW	0x0
0	stoppclk	The application sets this bit to stop the PHY clock (phy_clk) when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts. **Value** **Description** 0x0 Disable Stop Pclk 0x1 Enable Stop Pclk	RW	0x0

USB Data FIFO Address Map

These regions, available in both Host and Device modes, are a push/pop FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Module Instance	Base Address
usb0	0xFFB00000
usb1	0xFFB40000

Table 18-4: USB Endpoint FIFO Address Ranges

Name	Description	Start Address Offset	End Address Offset
EP0/HC0 FIFO	This address space is allocated for Endpoint 0/Host Channel 0 push/pop FIFO access.	0x1000	0x1FFF
EP1/HC1 FIFO	This address space is allocated for Endpoint 1/Host Channel 1 push/pop FIFO access.	0x2000	0x2FFF

SPI Controller 19

2015.11.02

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two serial peripheral interface (SPI) masters and two SPI slaves. The SPI masters and slaves are instances of the Synopsys® DesignWare® Synchronous Serial Interface (SSI) controller (DW_apb_ssi). †[58]

Features of the SPI Controller

The SPI controller has the following features: †

- Serial master and serial slave controllers – Enable serial communication with serial-master or serial-slave peripheral devices. †
- Serial interface operation – Programmable choice of the following protocols:
  - Motorola SPI protocol
  - Texas Instruments Synchronous Serial Protocol
  - National Semiconductor Microwire
- DMA controller interface integrated with HPS DMA controller
- SPI master supports `rxd` sample delay
- Transmit and receive FIFO buffers are 256 words deep
- SPI master supports up to four slave selects
- Programmable master serial bit rate
- Programmable data item size of 4 to 16 bits
- Support for Multi-master mode through the FPGA logic

SPI Block Diagram and System Integration

The SPI supports data bus widths of 32 bits. †

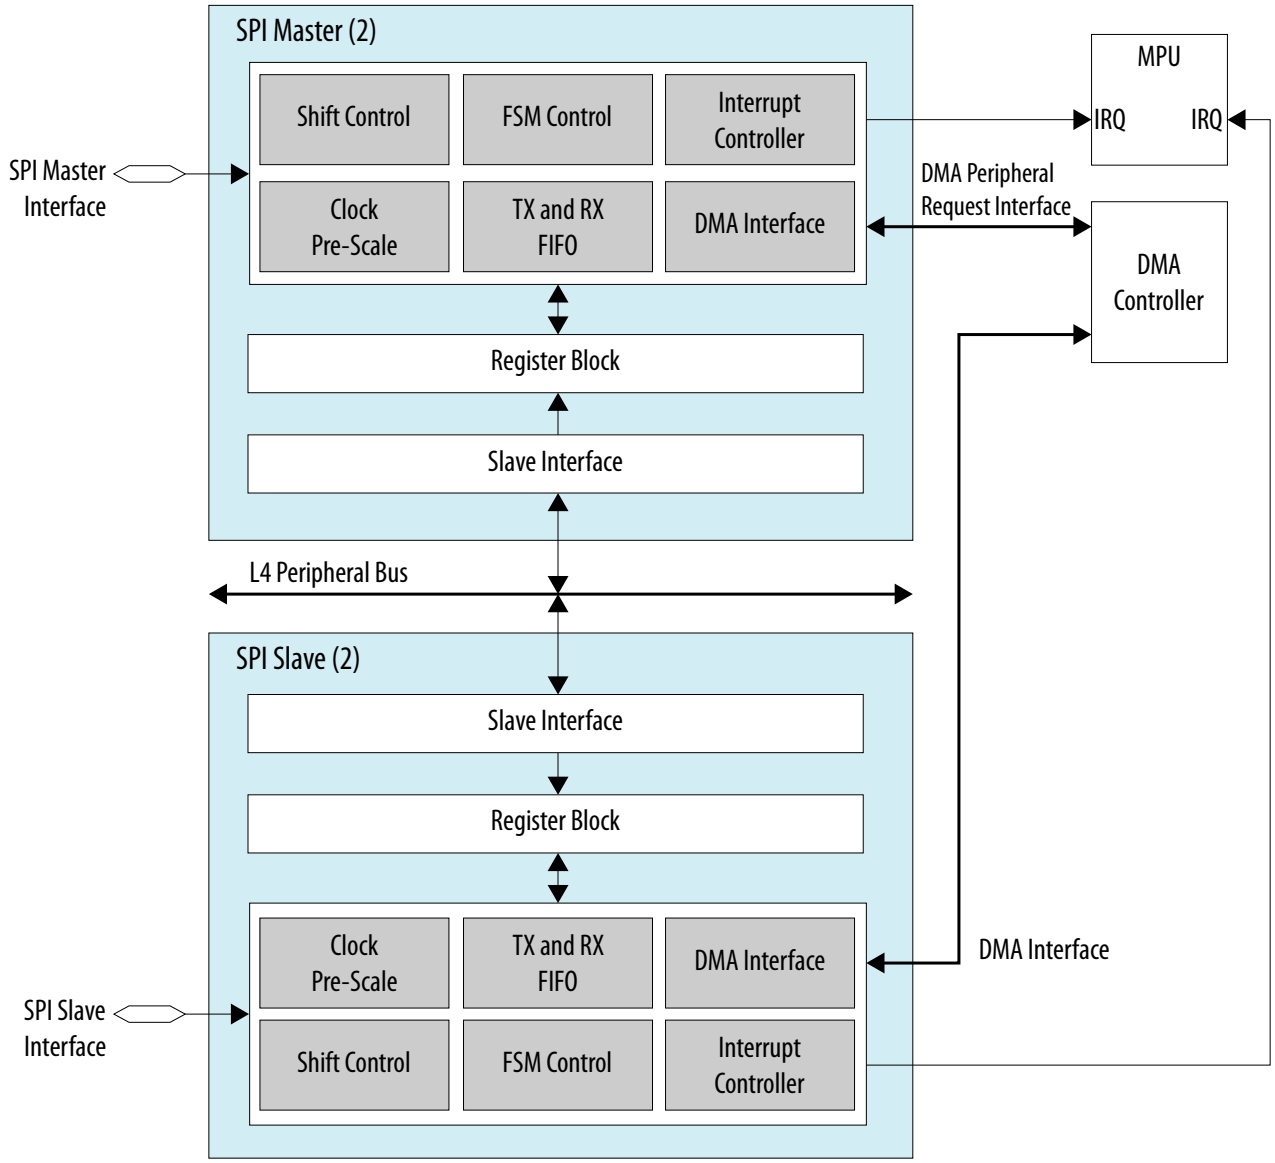
SPI Block Diagram

Figure 19-1: SPI Block Diagram



The functional groupings of the main interfaces to the SPI block are as follows: †

- System bus interface
- DMA peripheral request interface
- Interrupt interface
- SPI interface

SPI Controller Signal Description

Signals from the two SPI masters and two SPI slaves can be routed to the FPGA or the HPS I/O pins. The following sections describe the signals available.

Interface to HPS I/O

Table 19-1: SPI Master Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	Out	Serial clock output from the SPI master
MOSI	1	Out	Transmit data line for the SPI master
MISO	1	In	Receive data line for the SPI master
SS0	1	Out	Slave Select 0 Slave select signal from SPI master
SS1	1	Out	Slave Select 1 Slave select signal from SPI master

Table 19-2: SPI Slave Interface Pins

CLK	1	In	Serial clock input to the SPI slave
MOSI	1	In	Receive data line for the SPI slave
MISO	1	Out	Transmit data line for the SPI slave
SS0	1	In	Slave select input to the SPI slave

FPGA Routing

Table 19-3: SPI Master Signals for FPGA routing:

Signal Name	Signal Width	Direction	Description
`spim_txd`	1	Out	Transmit data line for the SPI master
`spim_rxd`	1	In	Receive data line for the SPI master
`spim_ss_in_n`	1	In	Master Contention Input

Signal Name	Signal Width	Direction	Description
spim_ssi_oe_n	1	Out	Output enable for the SPI master
spim_ss_0_n	1	Out	Slave Select 0 Slave select signal from SPI master
spim_ss_1_n	1	Out	Slave Select 1 Allows second slave to be connected to this master
spim_ss_2_n	1	Out	Slave Select 2 Allows third slave to be connected to this master
spim_ss_3_n	1	Out	Slave Select 3 Allows fourth slave to be connected to this master

Table 19-4: SPI Slave Signals for FPGA Routing

spis_txd	1	Out	Transmit data line for the SPI slave
spis_rxd	1	In	Receive data line for the SPI slave
spis_ss_in_n	1	In	Master Contention Input
spis_ssi_oe_n	1	Out	Output enable for the SPI slave
spis_sclk_in	1	In	Serial clock input

Functional Description of the SPI Controller

Protocol Details and Standards Compliance

This section describes the functional operation of the SPI controller.

The host processor accesses data, control, and status information about the SPI controller through the system bus interface. The SPI also interfaces with the DMA Controller. †

The HPS includes two general-purpose SPI master controllers and two general-purpose SPI slave controllers.

The SPI controller can connect to any other SPI device using any of the following protocols:

- Motorola SPI Protocol †
- Texas Instruments Serial Protocol (SSP) †
- National Semiconductor Microwire Protocol †

SPI Controller Overview

In order for the SPI controller to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces: †

- Motorola SPI protocol – A four-wire, full-duplex serial protocol from Motorola. The slave select line is held high when the SPI controller is idle or disabled. For more information, refer to "Motorola SPI Protocol". †
- Texas Instruments Serial Protocol (SSP) – A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol. For more information, refer to "Texas Instruments Synchronous Serial Protocol (SSP)". †
- National Semiconductor Microwire – A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave. For more information, refer to "National Semiconductor Microwire Protocol". You can program the FRF (frame format) bit field in the Control Register 0 (`CTRLR0`) to select which protocol is used. †

The serial protocols supported by the SPI controller allow for serial slaves to be selected or addressed using hardware. Serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in part A in the following figure. †

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. †

The main program in the software domain controls selection of the target slave device; this architecture is illustrated in part B of the Hardware/Software Slave Selection diagram. Software would control which slave is to respond to the serial transfer request from the master device. †

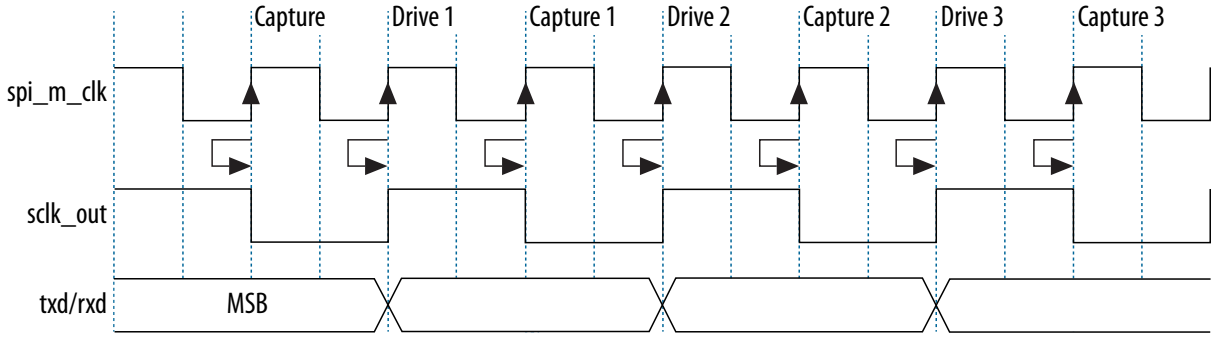
Serial Bit-Rate Clocks

SPI Master Bit-Rate Clock

The maximum frequency of the SPI master bit-rate clock (`sclk_out`) is one-half the frequency of SPI master clock (`spi_m_clk`). This allows the shift control logic to capture data on one clock edge of `sclk_out` and propagate data on the opposite edge. The `sclk_out` line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates. †

Figure 19-3: Maximum sclk_out/spi_m_clk Ratio



The frequency of `sclk_out` can be derived from the equation below, where <*SPI clock*> is `spi_m_clk` for the master SPI modules and `l4_main_clk` for the slave SPI modules. †

$F_{sclk_out} = F_{<SPI\ clock>}$ / SCKDV

SCKDV is a bit field in the register BAUDR, holding any even value in the range 2 to 65,534. If SCKDV is 0, then sclk_out is disabled. †

The following equation describes the frequency ratio restrictions between the bit-rate clock sclk_out and the SPI master peripheral clock. The SPI master peripheral clock must be at least double the offchip master clock. †

Table 19-5: SPI Master Peripheral Clock

SPI Master Peripheral Clock
$F_{spi_m_clk}$ >= 2 x (maximum F_{sclk_out}) †

SPI Slave Bit-Rate Clock

The minimum frequency of l4_main_clk depends on the operation of the slave peripheral. If the slave device is *receive only*, the minimum frequency of l4_main_clk is six times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). The sclk_in signal is double synchronized to the l4_main_clk domain, and then it is edge detected; this synchronization requires three l4_main_clk periods. †

If the slave device is *transmit and receive*, the minimum frequency of l4_main_clk is eight times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). This ensures that data on the master rxd line is stable before the master shift control logic captures the data. †

The frequency ratio restrictions between the bit-rate clock sclk_in and the SPI slave peripheral clock are as follows: †

- Slave (receive only): $F_{l4_main_clk}$ >= 6 multiply (maximum F_{sclk_in}) †
- Slave: $F_{l4_main_clk}$ >= 8 multiply (maximum F_{sclk_in}) †

Transmit and Receive FIFO Buffers

There are two 16-bit FIFO buffers, a transmit FIFO buffer and a receive FIFO buffer, with a depth of 256. Data frames that are less than 16 bits in size must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer. †

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO buffer location; for example, you may not store two 8-bit data frames in a single FIFO buffer location. If an 8-bit data frame is required, the upper 8-bits of the FIFO buffer entry are ignored or unused when the serial shifter transmits the data. †

The transmit and receive FIFO buffers are cleared when the SPI controller is disabled (SSIENR=0) or reset.

The transmit FIFO buffer is loaded by write commands to the SPI data register (DR). Data are popped (removed) from the transmit FIFO buffer by the shift control logic into the transmit shift register. The transmit FIFO buffer generates a transmit FIFO empty interrupt request when the number of entries in the FIFO buffer is less than or equal to the FIFO buffer threshold value. The threshold value, set through the register TXFTLR, determines the level of FIFO buffer entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO buffer is nearly empty. A Transmit FIFO Overflow Interrupt is generated if you attempt to write data into an already full transmit FIFO buffer. †

Data are popped from the receive FIFO buffer by read commands to the SPI data register (DR). The receive FIFO buffer is loaded from the receive shift register by the shift control logic. The receive FIFO buffer generates a receive FIFO full interrupt request when the number of entries in the FIFO buffer is greater than or equal to the FIFO buffer threshold value plus one. The threshold value, set through register RXFTLR, determines the level of FIFO buffer entries at which an interrupt is generated. †

The threshold value allows you to provide early indication to the processor that the receive FIFO buffer is nearly full. A Receive FIFO Overrun Interrupt is generated when the receive shift logic attempts to load data into a completely full receive FIFO buffer. However, the newly received data are lost. A Receive FIFO Underflow Interrupt is generated if you attempt to read from an empty receive FIFO buffer. This alerts the processor that the read data are invalid. †

Reset Manager on page 3-1
For more information, refer to the*Reset Manager* chapter.

SPI Interrupts

The SPI controller supports combined interrupt requests, which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking. All SPI interrupts have active-high polarity level. The SPI interrupts are described as follows: †

- Transmit FIFO Empty Interrupt – Set when the transmit FIFO buffer is equal to or below its threshold value and requires service to prevent an underrun. The threshold value, set through a software-programmable register, determines the level of transmit FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level. †
- Transmit FIFO Overflow Interrupt – Set when a master attempts to write data into the transmit FIFO buffer after it has been completely filled. When set, new data writes are discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (TXOICR). †
- Receive FIFO Full Interrupt – Set when the receive FIFO buffer is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level. †
- Receive FIFO Overflow Interrupt – Set when the receive logic attempts to place data into the receive FIFO buffer after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (RXOICR). †
- Receive FIFO Underflow Interrupt – Set when a system bus access attempts to read from the receive FIFO buffer when it is empty. When set, zeros are read back from the receive FIFO buffer. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (RXUICR). †
- Combined Interrupt Request – ORed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other SPI interrupt requests. †

Transmit FIFO Overflow, Transmit FIFO Empty, Receive FIFO Full, Receive FIFO Underflow, and Receive FIFO Overflow interrupts can all be masked independently, using the Interrupt Mask Register (IMR). †

Transfer Modes

When transferring data on the serial bus, the SPI controller operates one of several modes. The transfer mode (TMOD) is set by writing to the TMOD field in control register 0 (CTRLR0).

Note: The transfer mode setting does not affect the duplex of the serial transfer. TMOD is ignored for Microwire transfers, which are controlled by the MWCR register. †

Transmit and Receive

When TMOD = 0, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. †

Transmit Only

When TMOD = 1, any receive data are ignored. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO buffer. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered. †

Receive Only

When TMOD = 2, the transmit data are invalid. In the case of the SPI slave, the transmit FIFO buffer is never popped in Receive Only mode. The `txd` output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered. †

EEPROM Read

Note: This transfer mode is only valid for serial masters. †

When TMOD = 3, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. This takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the SPI master is transmitting data on its `txd` line, data on the `rxd` line is ignored). The SPI master continues to transmit data until the transmit FIFO buffer is empty. You should ONLY have enough data frames in the transmit FIFO buffer to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO buffer than are needed, then Read data is lost. †

When the transmit FIFO buffer becomes empty (all control information has been sent), data on the receive line (`rxd`) is valid and is stored in the receive FIFO buffer; the `txd` output is held at a constant logic level. The serial transfer continues until the number of data frames received by the SPI master matches the value of the NDF field in the `CTRLR1` register plus one. †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

SPI Master

The SPI master initiates and controls all serial transfers with serial-slave peripheral devices. †

The serial bit-rate clock, generated and controlled by the SPI controller, is driven out on the `sclk_out` line. When the SPI controller is disabled, no serial transfers can occur and `sclk_out` is held in "inactive" state, as defined by the serial protocol under which it operates. †

Related Information

SPI Block Diagram on page 19-2

RXD Sample Delay

The SPI master device is capable of delaying the default sample time of the rxd signal in order to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the sclk_out signal from the master and the rxd signal from the slave can mean that the timing of the rxd signal, as seen by the master, has moved away from the normal sampling time.

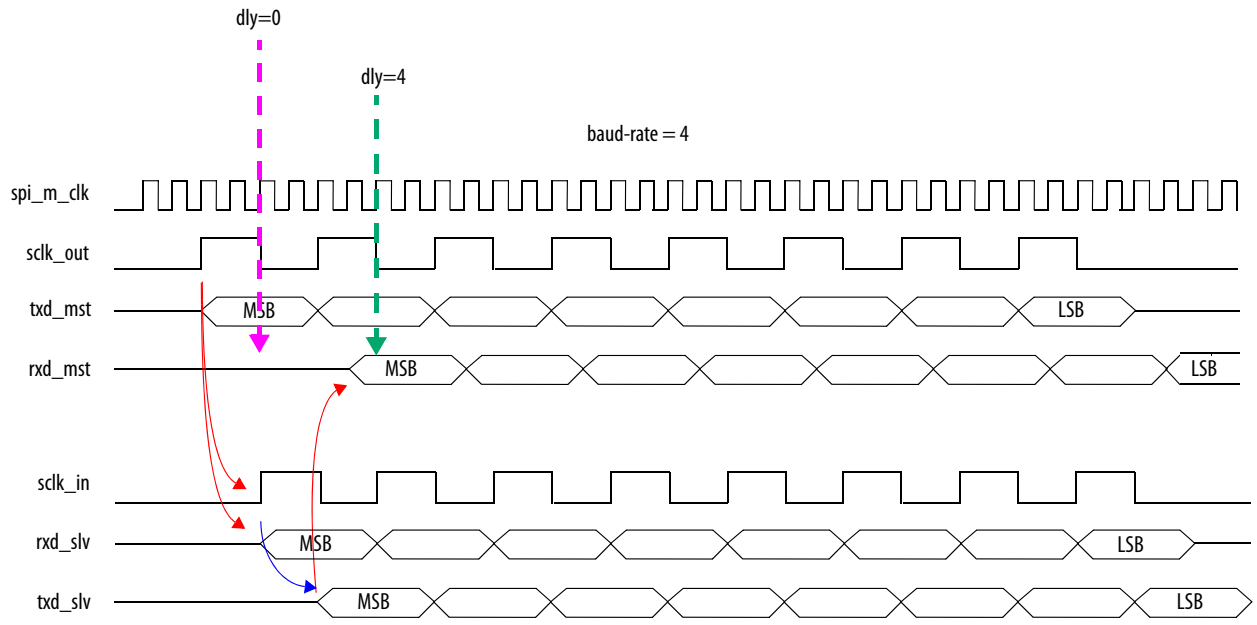
Without the RXD sample delay, you must increase the baud rate for the transfer in order to ensure that the setup times on the rxd signal are within range. This reduces the frequency of the serial interface.

Additional logic is included in the SPI master to delay the default sample time of the rxd signal. This additional logic can help to increase the maximum achievable frequency on the serial bus. †

By writing to the rsd field of the RX Sample Delay Register (rx_sample_dly), you specify an additional amount of delay applied to the rxd sample. The delay is in number of l4_main_clk clock cycles, with 64 maximum cycles allowed (zero is reserved). If the rsd field is programmed with a value exceeding 64, a zero delay is applied to the rxd sample.

The sample delay logic has a resolution of one l4_main_clk cycle. Software can "train" the serial bus by coding a loop that continually reads from the slave and increments the master's RXD Sample Delay value until the correct data is received by the master. †

Figure 19-4: Effects of Round Trip Routing Delays on sclk_out Signal



Red arrows indicates routing delay between master and slave devices
Blue arrow indicates sampling delay within slave from receiving slk_in to driving txd out

Data Transfers

The SPI master starts data transfers when all the following conditions are met:

- The SPI master is enabled
- There is at least one valid entry in the transmit FIFO buffer
- A slave device is selected

When actively transferring data, the busy flag (BUSY) in the status register (SR) is set. You must wait until the busy flag is cleared before attempting a new serial transfer. †

Note: The BUSY status is not set when the data are written into the transmit FIFO buffer. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO buffer, the shift logic does not begin the serial transfer until a positive edge of the sclk_out signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the BUSY status, you should first poll the Transit FIFO Empty (TFE) status (waiting for 1) or wait for (BAUDR * SPI clock) clock cycles. †

Master SPI and SSP Serial Transfers

"Motorola SPI Protocol" and "Texas Instruments Synchronous Serial Protocol (SSP)" describe the SPI and SSP serial protocols, respectively. †

When the transfer mode is "transmit and receive" or "transmit only" (TMOD = 0 or TMOD = 1, respectively), transfers are terminated by the shift control logic when the transmit FIFO buffer is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor indicating that the transmit FIFO buffer is nearly empty. †

When the DMA is used in conjunction with the SPI master, the transmit data level (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO buffer entries) into the transmit FIFO buffer before enabling a serial slave. This ensures that serial transmission does not begin until the number of data frames that make up the continuous transfer are present in the transmit FIFO buffer. †

When the transfer mode is "receive only" (TMOD = 2), a serial transfer is started by writing one "dummy" data word into the transmit FIFO buffer when a serial slave is selected. The txd output from the SPI controller is held at a constant logic level for the duration of the serial transfer. The transmit FIFO buffer is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the "number of data frames" (NDF) field in control register 1 (CTRLR1). †

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the NDF field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the NDF value plus one. This transfer mode increases the bandwidth of the system bus as the transmit FIFO buffer never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. †

When the transfer mode is "eeprom_read" (TMOD = 3), a serial transfer is started by writing the opcode and/or address into the transmit FIFO buffer when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO buffer. The end of the serial transfer is controlled by the NDF field in the control register 1 (CTRLR1). †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

The receive FIFO threshold level (RXF TLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA is used, the receive data level (DMARDLR) can be used to early request the DMA Controller, indicating that the receive FIFO buffer is nearly full. †

Master Microwire Serial Transfers

"National Semiconductor Microwire Protocol" describes the Microwire serial protocol in detail. †

Microwire serial transfers from the SPI serial master are controlled by the Microwire Control Register (MWCR). The MHS bit field enables and disables the Microwire handshaking interface. The MDD bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The MWMOD bit field defines whether the transfer is sequential or nonsequential. †

All Microwire transfers are started by the SPI serial master when there is at least one control word in the transmit FIFO buffer and a slave is enabled. When the SPI master transmits the data frame (MDD =1), the transfer is terminated by the shift logic when the transmit FIFO buffer is empty. When the SPI master receives the data frame (MDD = 1), the termination of the transfer depends on the setting of the MWMOD bit field. If the transfer is nonsequential (MWMOD = 0), it is terminated when the transmit FIFO buffer is empty after shifting in the data frame from the slave. When the transfer is sequential (MWMOD = 1), it is terminated by the shift logic when the number of data frames received is equal to the value in the CTRLR1 register plus one. †

When the handshaking interface on the SPI master is enabled (MHS =1), the status of the target slave is polled after transmission. Only when the slave reports a *ready status* does the SPI master complete the transfer and clear its BUSY status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a *ready status*. †

Related Information

National Semiconductor Microwire Protocol on page 19-19

SPI Slave

The SPI slave handles serial communication with transfer initiated and controlled by serial master peripheral devices.

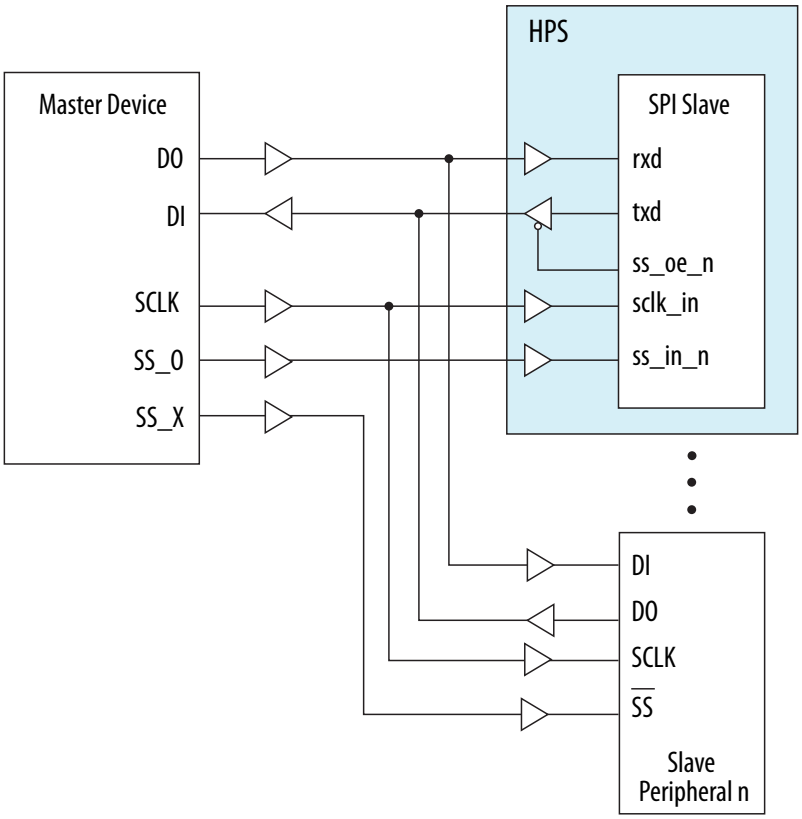
- sclk_in—serial clock to the SPI slave †
- ss_in_n—slave select input to the SPI slave †
- ss_oe_n—output enable for the SPI master or slave †
- txd—transmit data line for the SPI master or slave †
- rxd—receive data line for the SPI master or slave †

When the SPI serial slave is selected, it enables its txd data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk_in), driven from the SPI master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge. †

When the SPI serial slave is not selected, it must not interfere with data transfers between the serial-master and other serial-slave devices. When the serial slave is not selected, its txd output is buffered, resulting in a high impedance drive onto the SPI master rxd line. The buffers shown in the SPI Slave diagram are external to SPI controller. spi_oe_n is the SPI slave output enable signal. †

The serial clock that regulates the data transfer is generated by the serial-master device and input to the SPI slave on `sclk_in`. The slave remains in an idle state until selected by the bus master. When not actively transmitting data, the slave must hold its `txd` line in a high impedance state to avoid interference with serial transfers to other slave devices. The SPI slave output enable (`ss_oe_n`) signal is available for use to control the `txd` output buffer. The slave continues to transfer data to and from the master device as long as it is selected. If the master transmits to all serial slaves, a control bit (`SLV_OE`) in the SPI control register 0 (`CTRLR0`) can be programmed to inform the slave if it should respond with data from its `txd` line. †

Figure 19-5: SPI Slave



The `slv_oe` bit in the control register is only valid if the SPI slave interface is routed to the FPGA. To use the SPI slave in a multi master system or in a system that requires the SPI slave TXD to be tri-stated, you can do the following:

- If you want the SPI slave to control the tri-state of TXD, it must be routed to the FPGA first and use the FPGA IO. HPS I/O can also be used via the Loan I/O interface (timing permitting).
- If you do not want to route to the FPGA, then software control of the TXD (tri-state) must be performed with the already included code to control via an HPS GPIO input. Please refer to the pin connection guidelines to find which GPIO pins correspond to which HPS SPI slave SS ports.

Slave SPI and SSP Serial Transfers

"Motorola SPI Protocol" and the "Texas Instruments Synchronous Serial Protocol (SSP)" contain a description of the SPI and SSP serial protocols, respectively. †

If the SPI slave is *receive only* (TMOD=2), the transmit FIFO buffer need not contain valid data because the data currently in the transmit shift register is resent each time the slave device is selected. The TXE error flag in the status register (SR) is not set when TMOD=2. You should mask the Transmit FIFO Empty Interrupt when this mode is used. †

If the SPI slave transmits data to the master, you must ensure that data exists in the transmit FIFO buffer before a transfer is initiated by the serial-master device. If the master initiates a transfer to the SPI slave when no data exists in the transmit FIFO buffer, an error flag (TXE) is set in the SPI status register, and the previously transmitted data frame is resent on txd. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level register (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor, indicating that the transmit FIFO buffer is nearly empty. When a DMA Controller is used, the DMA transmit data level register (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. †

The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. The receive FIFO threshold level register (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA Controller is used, the DMA receive data level register (DMARDLR) can be used to early request the DMA controller, indicating that the receive FIFO buffer is nearly full. †

Serial Transfers

"National Semiconductor Microwire Protocol" describes the Microwire serial protocol in detail, including timing diagrams and information about how data are structured in the transmit and receive FIFO buffers before and after a serial transfer. The Microwire protocol operates in much the same way as the SPI protocol. There is no decode of the control frame by the SPI slave device. †

Related Information

National Semiconductor Microwire Protocol on page 19-19

Glue Logic for Master Port ss_in_n

When configured as a master, the SPI has an input, ssi_in_n, which can be used by the deciding logic in a multi-master system to disable one master when another has priority. The polarity of this signal depends on the serial protocol in use, and the protocol is dynamically selectable.

Note: The signals necessary to support multi-master mode are only provided through the FPGA logic.

The table below lists the three protocols and the effect of ss_in_n on the ability of the master to transfer data. Note that for the SSP protocol the effect of ss_in_n is inverted with respect to the other protocols.

Protocol	ss_in_n value	Effect on Serial Transfer
Motorola SPI	1	Enabled
	0	Disabled
National Semiconductor Microwire	1	Enabled
	0	Disabled

Protocol	ss_in_n value	Effect on Serial Transfer
Texas Instruments Serial Protocol (SSP)	1	Disabled
	0	Enabled

Figure 19-6: Arbitration Between Multiple Serial Masters

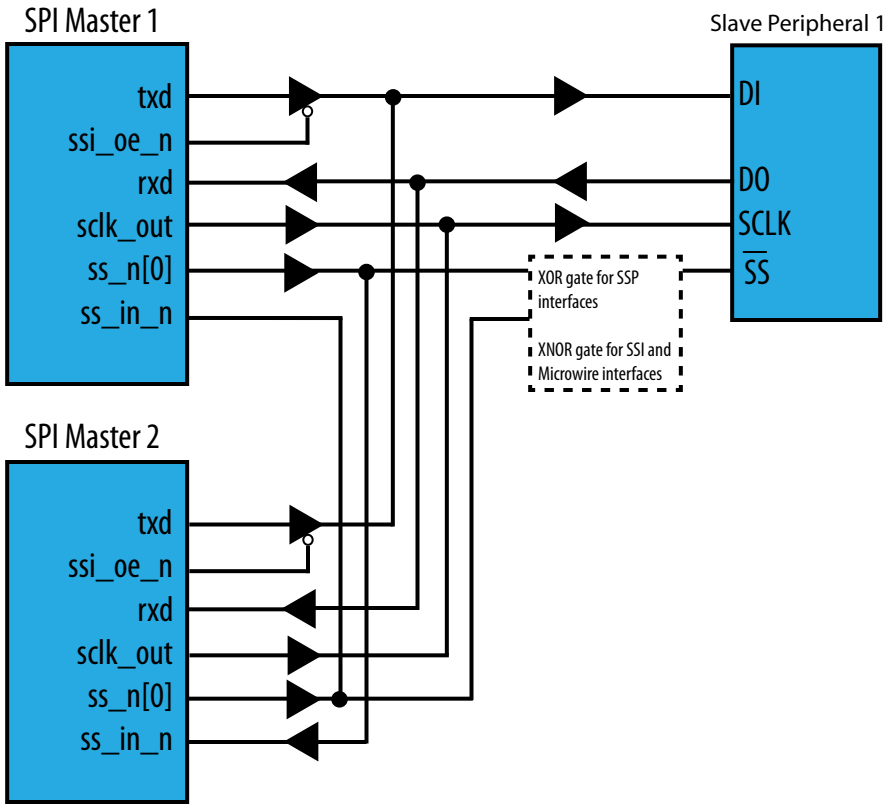

Figure 19-7: SPI Configured as Master Device

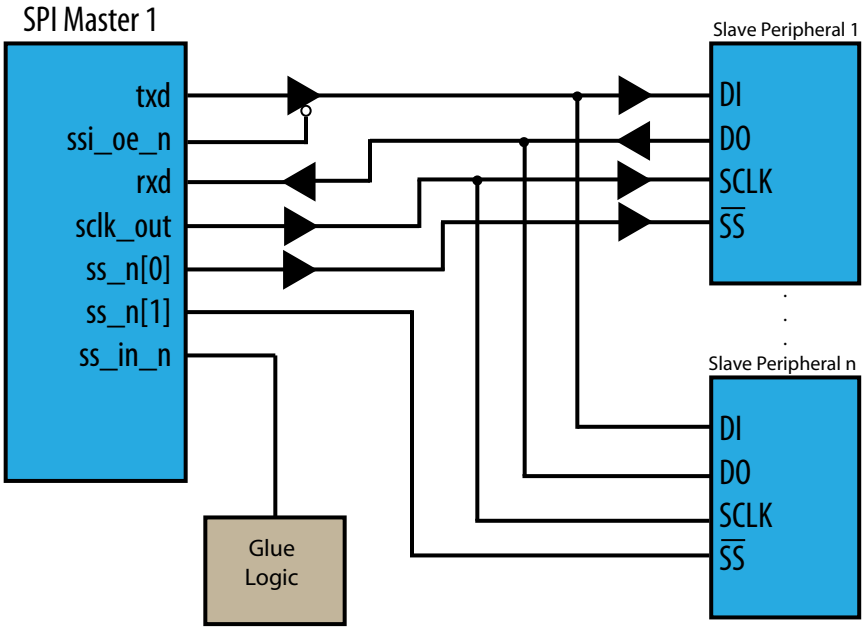


Partner Connection Interfaces

The SPI can connect to any serial-master or serial-slave peripheral device using one of several interfaces.

Motorola SPI Protocol

The inactive state of the serial clock is low. The data frame can be 4 to 16 bits in length. †

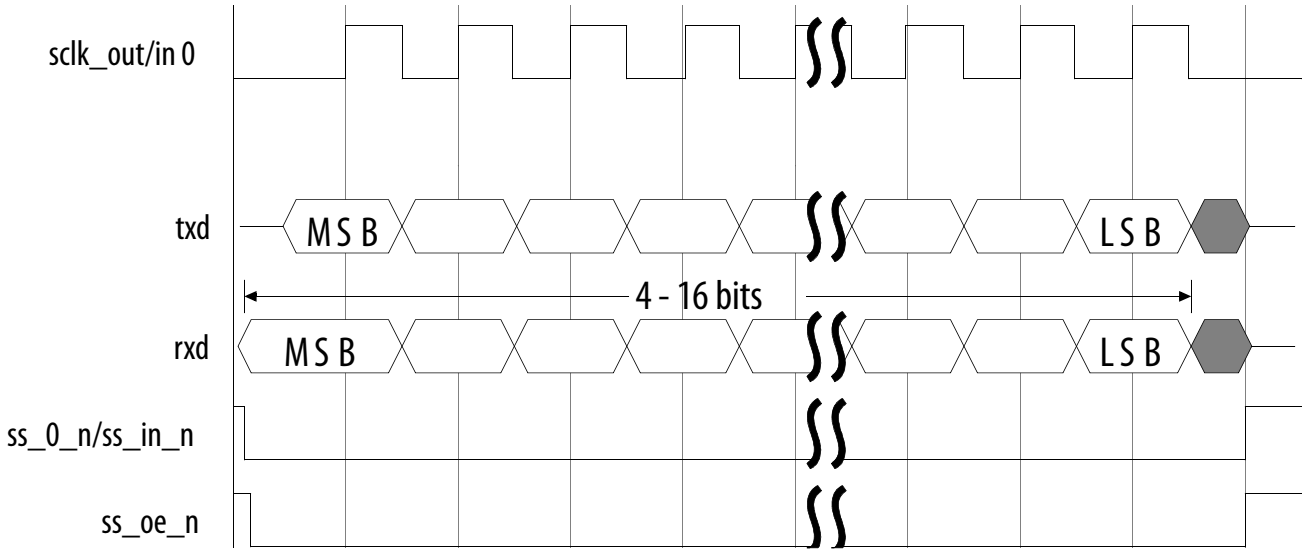
Data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the `txd` and `rxd` lines prior to the first serial clock edge. †

The slave select signal takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

The following signals are illustrated in the timing diagrams in this section: †

- sclk_out—serial clock from SPI master †
- sclk_in—serial clock from SPI slave †
- ss_0_n—slave select signal from SPI master †
- ss_oe_n—output enable for the SPI master or slave †
- txd—transmit data line for the SPI master or slave †
- rxd—receive data line for the SPI master or slave †

Figure 19-8: SPI Serial Format



There are four possible transfer modes on the SPI controller for performing SPI serial transactions; refer to "Transfer Modes" . For *transmit and receive transfers* (transfer mode field (9:8) of the Control Register 0 = 0), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

Note: For *transmit only* transfers (transfer mode field (9:8) of the Control Register 0 = 1), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. As the data received from the external serial device is deemed invalid, it is not stored in the SPI receive FIFO buffer. †

For *receive only* transfers (transfer mode field (9:8) of the Control Register 0 = 2), data transmitted from the SPI controller to the external serial device is invalid, so a single dummy word is written into the transmit FIFO buffer to begin the serial transfer. The txd output from the SPI controller is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

For EEPROM read transfers (transfer mode field [9:8] of the Control Register 0 = 3), opcode and/or EEPROM address are written into the transmit FIFO buffer. During transmission of these control frames, received data is not captured by the SPI master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO buffer.

SPI Serial Format

Two different modes of continuous data transfers are supported when SCPH = 0 and 1.†

- When clock phase SCPH = 0, the SPI Controller deasserts the slave select signal between each data word and the serial clock is held to its default value while the slave select signal is deasserted.†
- When SCPH = 1, the slave select is held asserted (active low) for the duration of the transfer.†

Figure 19-9: Serial Format Continuous Transfers (SCPH =0)

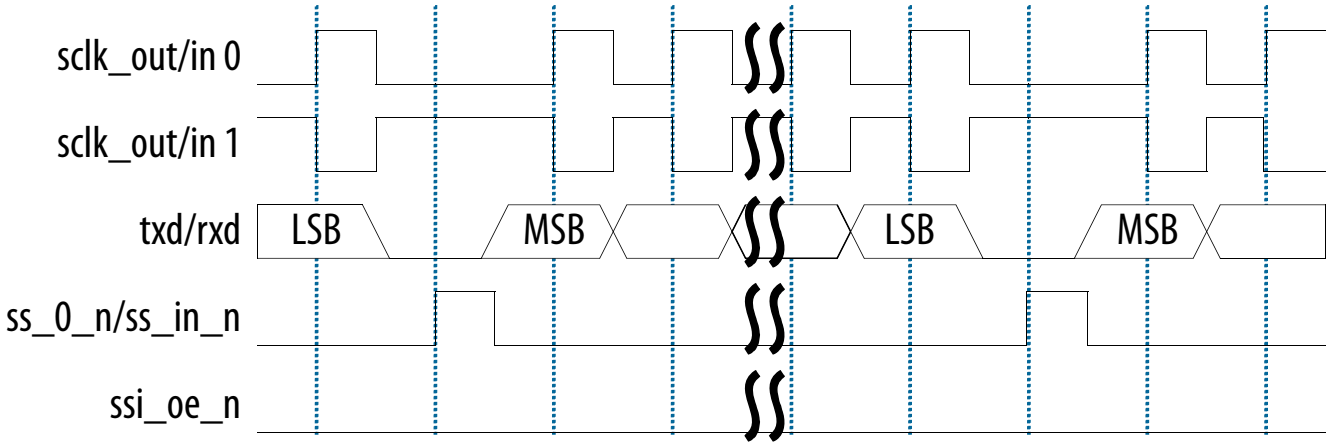


Figure 19-10: Serial Format Continuous Transfers (SCPH =1)

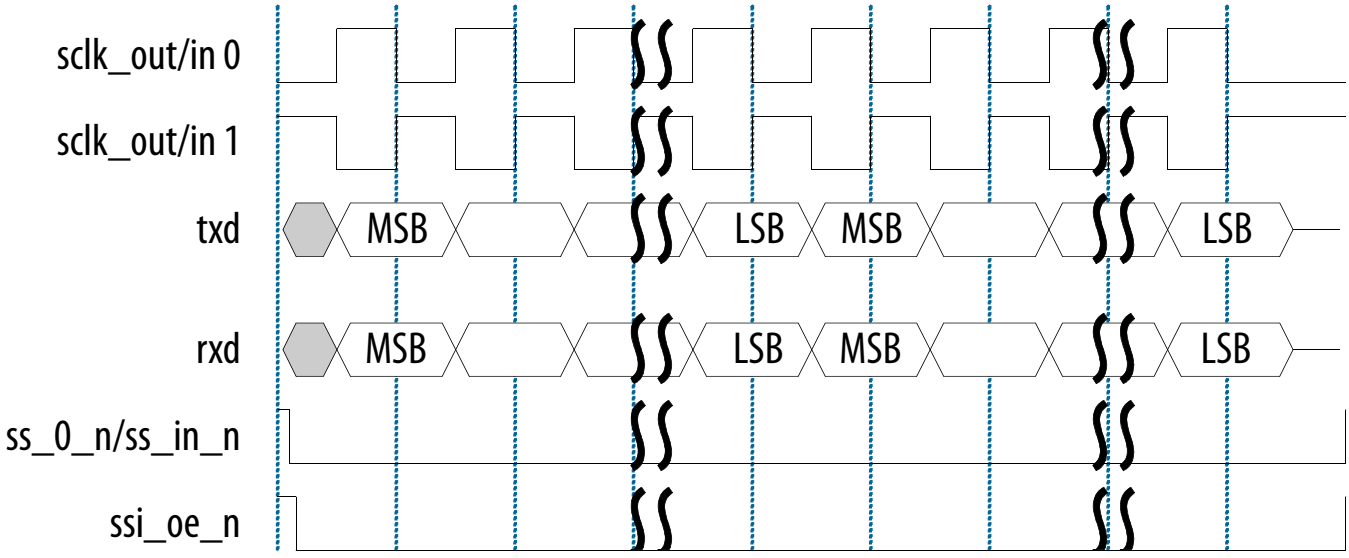


Related Information

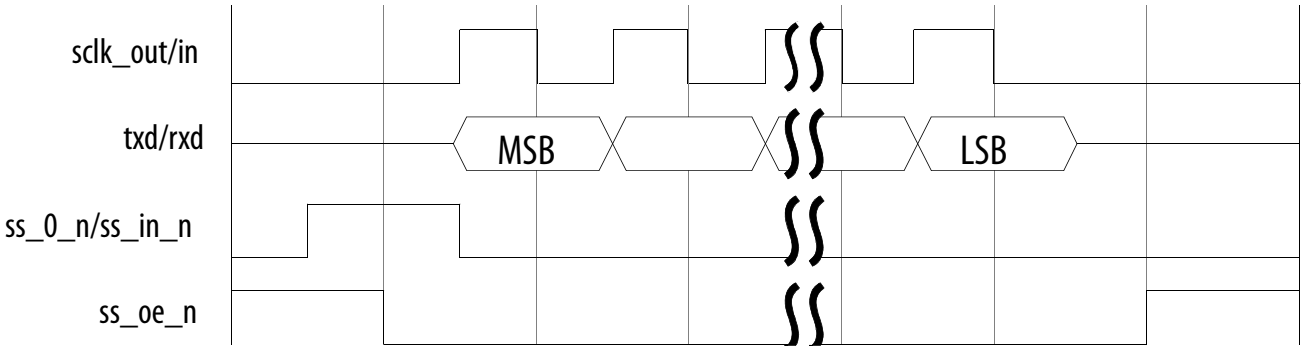
Transfer Modes on page 19-8

Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (`ss_0_n`) for one serial clock period. Data to be transmitted are driven onto the `txd` line one serial clock cycle later; similarly data from the slave are driven onto the `rxd` line. Data are propagated on the rising edge of the serial clock (`sclk_out/sclk_in`) and captured on the falling edge. The length of the data frame ranges from 4 to 16 bits.

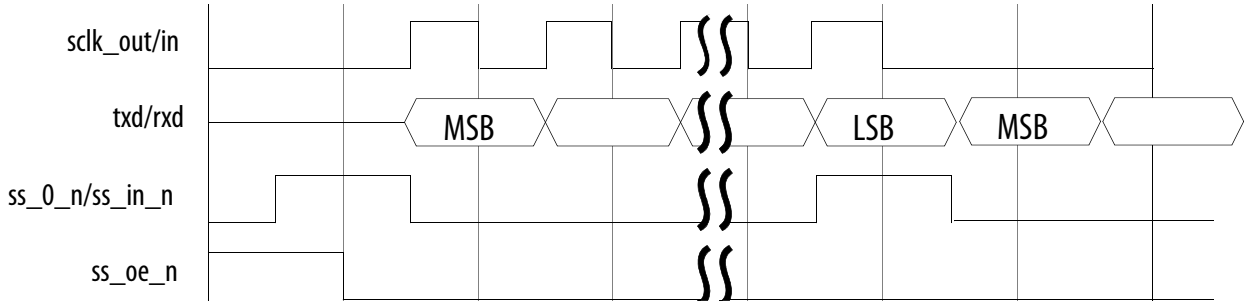
Note: The slave select signal (`ss_0_n`) takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

Figure 19-11: SSP Serial Format



Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows. †

Figure 19-12: SSP Serial Format Continuous Transfer



National Semiconductor Microwire Protocol

For the master SPI, data transmission begins as soon as the output enable signal is deasserted. One-half serial clock (`sclk_out`) period later, the first bit of the control is sent out on the `txd` line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in `CTRLR0`. The remainder of the control word is transmitted (propagated on the falling edge of `sclk_ou t`) by the SPI serial master. During this transmission, no data are present (high impedance) on the serial master's `rxd` line. †

The direction of the data word is controlled by the `MDD` bit field (bit 1) in the Microwire Control Register (`MWCR`). When `MDD`=0, this indicates that the SPI serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be 4 to 16 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge. †

Continuous transfers from the Microwire protocol can be sequential or nonsequential, and are controlled by the `MWMOD` bit field (bit 0) in the `MWCR`. †

Nonsequential continuous transfers occur, with the control word for the next transfer following immediately after the LSB of the current data word. †

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer. †

During sequential continuous transfers, only one control word is transmitted from the SPI master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the SPI master terminates the transfer when the number of words received is equal to the value in the CTRLR1 register plus one. †

When MDD = 1, this indicates that the SPI serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the SPI master begins transmitting the data frame to the slave peripheral. †

Note: The SPI controller does not support continuous sequential Microwire writes, where MDD = 1 and MWMOD = 1. †

Continuous transfers occur with the control word for the next transfer following immediately after the LSB of the current data word.

The Microwire handshaking interface can also be enabled for SPI master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the MHS bit field (bit 2) on the MWCR register. When MHS is set to 1, the SPI serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers. †

After the first data word has been transmitted to the serial-slave device, the SPI master polls the rxd input waiting for a ready status from the slave device. Upon reception of the ready status, the SPI master begins transmission of the next control word. After transmission of the last data frame has completed, the SPI master transmits a start bit to clear the ready status of the slave device before completing the transfer. †

In the SPI slave, data transmission begins with the falling edge of the slave select signal (ss_in_0). One-half serial clock (sclk_in) period later, the first bit of the control is present on the rxd line. The length of the control word can be in the range of 1 to 16 bits and is set by writing bit field CFS in the CTRLR0 register. The CFS bit field must be set to the size of the expected control word from the serial master. The remainder of the control word is received (captured on the rising edge of sclk_in) by the SPI serial slave. During this reception, no data are driven (high impedance) on the serial slave's txd line. †

The direction of the data word is controlled by the MDD bit field (bit 1) MWCR register. When MDD=0, this indicates that the SPI serial slave is to receive data from the external serial master. Immediately after the control word is transmitted, the serial master begins to drive the data frame onto the SPI slave rxd line. Data are propagated on the falling edge of the serial clock and captured on the rising edge. The slave-select signal is held active-low during the transfer and is deasserted one-half clock cycle later after the data are transferred. The SPI slave output enable signal is held inactive for the duration of the transfer. †

When MDD=1, this indicates that the SPI serial slave transmits data to the external serial master. Immediately after the LSB of the control word is transmitted, the SPI slave transmits a dummy 0 bit, followed by the 4- to 16-bit data frame on the txd line. †

Continuous transfers for a SPI slave occur in the same way as those specified for the SPI master. The SPI slave does not support the handshaking interface, as there is never a busy period. †

Figure 19-13: Single SPI Serial Master Microwire Serial Transfer (MDD=0)

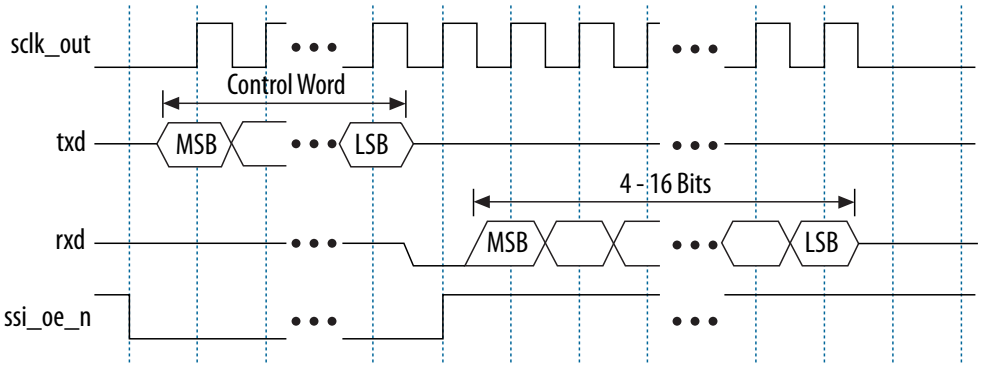


Figure 19-14: Single SPI Slave Microwire Serial Transfer (MDD=1)

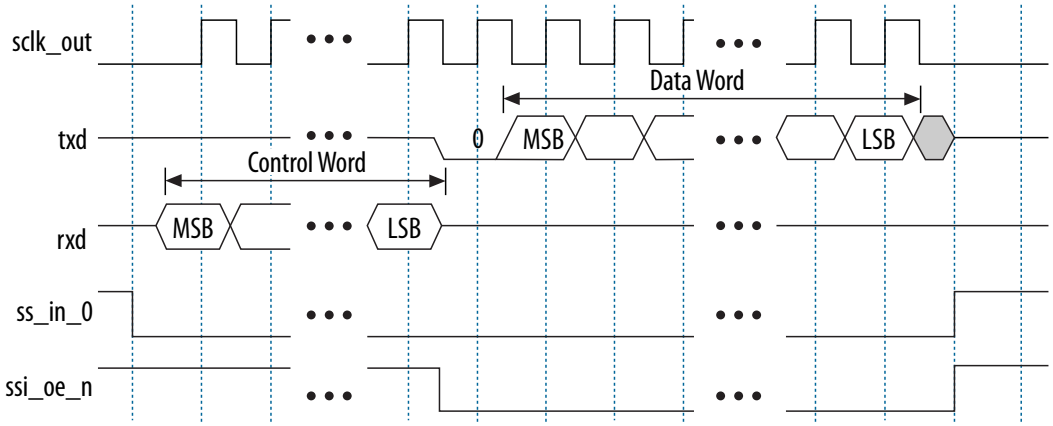


DMA Controller Interface

The SPI controller supports DMA signaling to indicate when the receive FIFO buffer has data ready to be read or when the transmit FIFO buffer needs data. It requires two DMA channels, one for transmit data and one for receive data. The SPI controller can issue single or burst DMA transfers and accepts burst acknowledges from the DMA. System software can trigger the DMA burst mode by programming an appropriate value into the threshold registers. The typical setting of the threshold register value is half full.

To enable the DMA Controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 into the TDMAE bit field of DMACR register enables the SPI transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the SPI receive handshaking interface. †

Slave Interface

The host processor accesses data, control, and status information about the SPI controller through the slave interface. The SPI supports a data bus width of 32 bits.

Control and Status Register Access

Control and status registers within the SPI controller are byte-addressable. The maximum width of the control or status register in the SPI controller is 16 bits. Therefore, all read and write operations to the SPI control and status registers require only one access. †

Data Register Access

The data register (DR) within the SPI controller is 16 bits wide in order to remain consistent with the maximum serial transfer size (data frame). A write operation to DR moves data from the slave write data bus into the transmit FIFO buffer. An read operation from DR moves data from the receive FIFO buffer onto the slave readback data bus. †

Note: The DR register in the SPI controller occupies sixty-four 32-bit locations of the memory map to facilitate burst transfers. There are no burst transactions on the system bus itself, but SPI supports bursts on the system interconnect. Writing to any of these address locations has the same effect as pushing the data from the slave write data bus into the transmit FIFO buffer. Reading from any of these locations has the same effect as popping data from the receive FIFO buffer onto the slave readback data bus. The FIFO buffers on the SPI controller are not addressable.

Clocks and Resets

The SPI controller uses the clock and reset signals shown in the following table.

Table 19-6: SPI Controller Clocks and Resets

	Master	Slave
SPI clock	spi_m_clk	l4_main_clk
SPI bit-rate clock	sclk_out	sclk_in
Reset	spim_rst_n	spis_rst_n

Taking the SPI Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

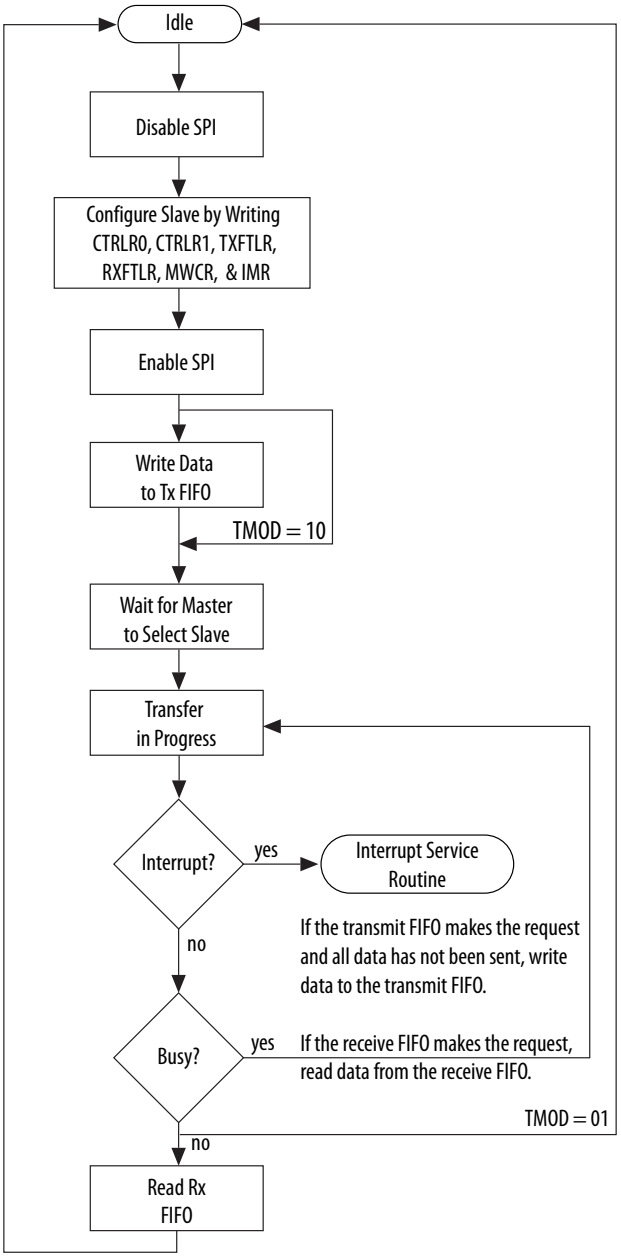
SPI Programming Model

This section describes the programming model for the SPI controller, for the following master and slave transfer types:

- Master SPI and SSP serial transfers
- Master Microwire serial transfers
- Slave SPI and SSP serial transfers
- Slave Microwire serial transfers
- Software Control for slave selection

Master SPI and SSP Serial Transfers

Figure 19-15: Master SPI or SSP Serial Transfer Software Flow



To complete an SPI or SSP serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to the SSI Enable register (`SSIENR`).
2. Set up the SPI master control registers for the transfer. You can set these registers in any order.

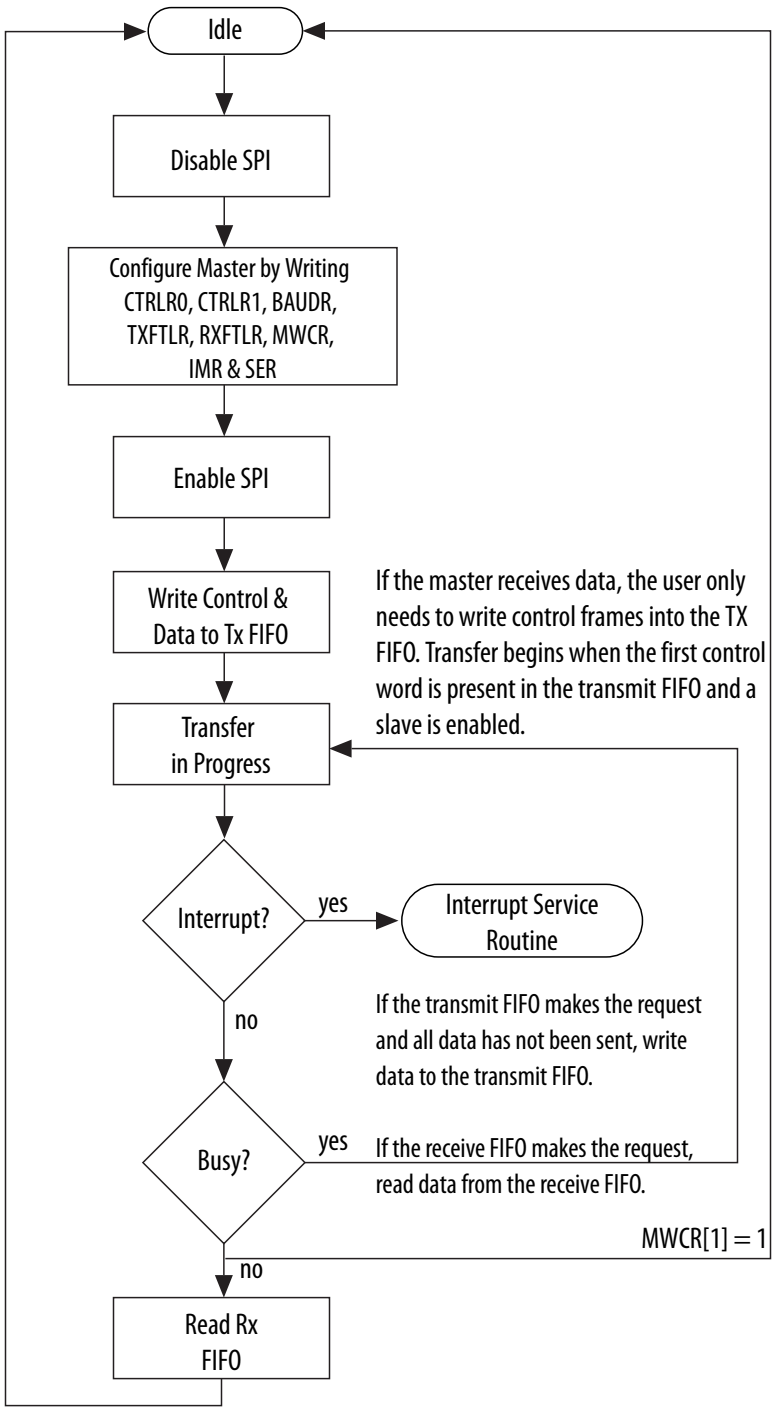
- Write Control Register 0 (CTRLLR0). For SPI transfers, you must set the serial clock polarity and serial clock phase parameters identical to the target slave device.
- If the transfer mode is receive only, write Control Register 1 (CTRLR1) with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
- Write the Baud Rate Select Register (BAUDR) to set the baud rate for the transfer.
- Write the Transmit and Receive FIFO Threshold Level registers (TXFTLR and RXFTLR) to set FIFO buffer threshold levels.
- Write the IMR register to set up interrupt masks.
- Write the Slave Enable Register (SER) register to enable the target slave for selection. If a slave is enabled at this time, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the Data Register (DR), the transfer does not begin until a slave is enabled.

3. Enable the SPI master by writing 1 to the SSIENR register.
4. Write data for transmission to the target slave into the transmit FIFO buffer (write DR). If no slaves were enabled in the SER register at this point, enable it now to begin the transfer.
5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).

6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is receive only (TMOD = 2), the shift control logic stops the transfer when the specified number of frames have been received. When the transfer is done, the BUSY status is reset to 0.
7. If the transfer mode is not transmit only (TMOD is not equal to 1), read the receive FIFO buffer until it is empty
8. Disable the SPI master by writing 0 to SSIENR.

Master Microwire Serial Transfers

Figure 19-16: Microwire Serial



To complete a Microwire serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
   - Write CTRLR0 to set transfer parameters. If the transfer is sequential and the SPI master receives data, write CTRLR1 with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
   - Write BAUDR to set the baud rate for the transfer.
   - Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
   - Write the IMR register to set up interrupt masks.

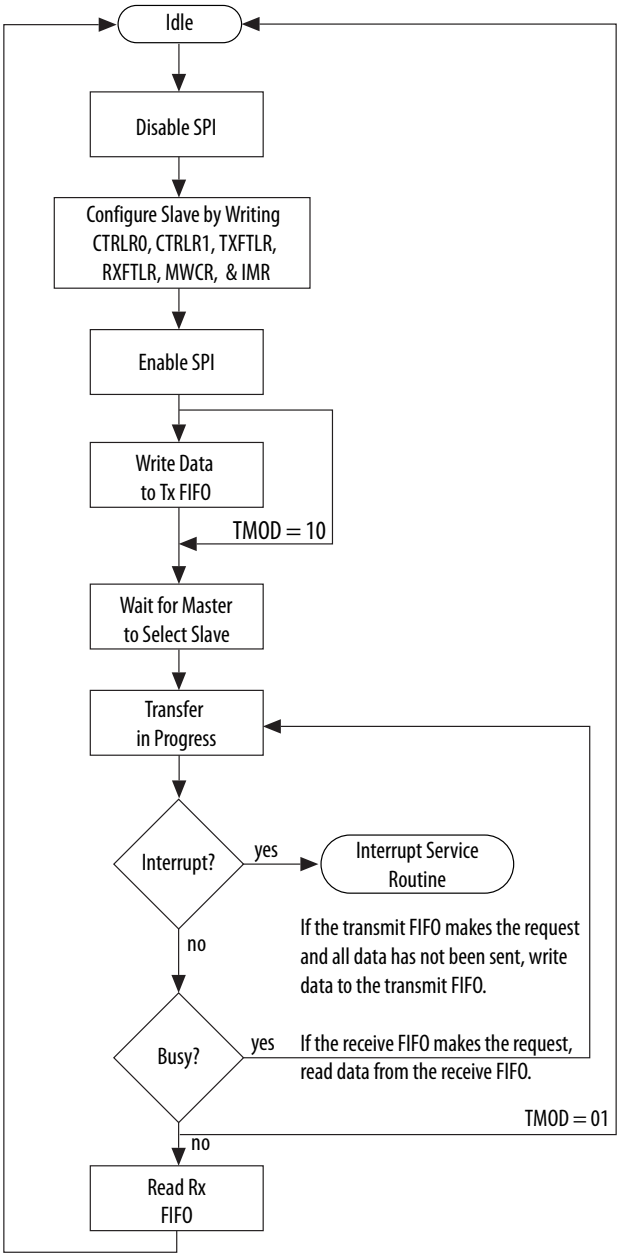
   You can write the SER register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the DR register, the transfer does not begin until a slave is enabled.
3. Enable the SPI master by writing 1 to the SSIENR register.
4. If the SPI master transmits data, write the control and data words into the transmit FIFO buffer (write DR). If the SPI master receives data, write the control word or words into the transmit FIFO buffer. If no slaves were enabled in the SER register at this point, enable now to begin the transfer.
5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is sequential and the SPI master receives data, the shift control logic stops the transfer when the specified number of data frames is received. When the transfer is done, the BUSY status is reset to 0.
7. If the SPI master receives data, read the receive FIFO buffer until it is empty.
8. Disable the SPI master by writing 0 to SSIENR.

Related Information

SPI Controller Address Map and Register Definitions on page 19-33

Slave SPI and SSP Serial Transfers

Figure 19-17: Slave SPI or SSP Serial Transfer Software Flow



To complete a continuous serial transfer from a serial master to the SPI slave, follow these steps:

1. If the SPI slave is enabled, disable it by writing 0 to `SSIENR`.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.

- Write CTRLR0 (for SPI transfers, set SCPH and SCPOL identical to the master device).
- Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
- Write the IMR register to set up interrupt masks.

3. Enable the SPI slave by writing 1 to the SSIENR register.
4. If the transfer mode is transmit and receive (TMOD= 0) or transmit only (TMOD= 1), write data for transmission to the master into the transmit FIFO buffer (write DR). If the transfer mode is receive only (TMOD= 2), you need not write data into the transmit FIFO buffer. The current value in the transmit shift register is retransmitted.
5. The SPI slave is now ready for the serial transfer. The transfer begins when a serial-master device selects the SPI slave.
6. When the transfer is underway, the BUSY status can be polled to return the transfer status. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
7. The transfer ends when the serial master removes the select input to the SPI slave. When the transfer is completed, the BUSY status is reset to 0.
8. If the transfer mode is not transmit only (TMOD != 1), read the receive FIFO buffer until empty.
9. Disable the SPI slave by writing 0 to SSIENR.

Slave Microwire Serial Transfers

For the SPI slave, the Microwire protocol operates in much the same way as the SPI protocol. The SPI slave does not decode the control frame.

Software Control for Slave Selection

When using software to select slave devices, the input select lines from serial slave devices is connected to a single slave select output on the SPI master.

Example: Slave Selection Software Flow for SPI Master

1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. If the transfer is receive only, write the number of frames into CTRLR1.
4. Write BAUDR to set the transfer baud rate.
5. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
6. Write IMR register to set interrupt masks.
7. Write SER register bit 0 to 1 to select slave 1 in this example.
8. Write SSIENR register bit 0 to 1 to enable SPI master.

Example: Slave Selection Software Flow for SPI Slave

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
4. Write IMR register to set interrupt masks.
5. Write SSIENR register bit 0 to 1 to enable SPI slave.
6. If the SPI slave transmits data, write data into TX FIFO buffer.

Note: All other SPI slaves are disabled (SSIENR = 0) and therefore will not respond to an active level on their ss_in_n port.

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the SPI controller is 256 entries.

DMA Controller Operation

To enable the DMA controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 to the TDMAE bit field of DMACR register enables the SPI controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the DMACR register enables the SPI controller receive handshaking.†

Related Information

DMA Controller on page 16-1
For details about the DMA controller, refer to the *DMA Controller* chapter.

Transmit FIFO Buffer Underflow

During SPI serial transfers, transmit FIFO buffer requests are made to the DMA Controller whenever the number of entries in the transmit FIFO buffer is less or equal to the value in DMA Transmit Data Level Register (DMATDLR); also known as the watermark level. The DMA Controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length.†

Note: Data should be fetched from the DMA often enough for the transmit FIFO buffer to perform serial transfers continuously, that is, when the FIFO buffer begins to empty, another DMA request should be triggered. Otherwise, the FIFO buffer will run out of data (underflow). To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA Controller* chapter.

Transmit FIFO Watermark

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the SPI transmits data to the rate at which the DMA can respond to destination burst requests. †

Example 1: Transmit FIFO Watermark Level = 64

Consider the example where the assumption is made: †

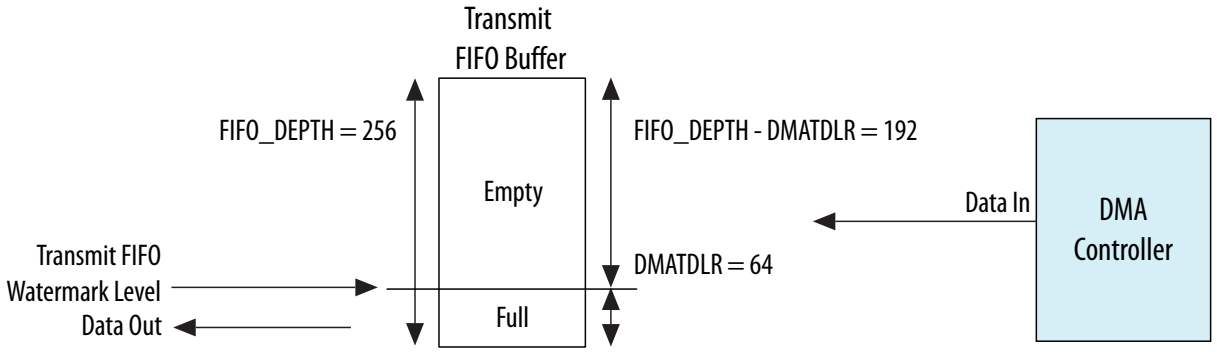
DMA burst length = FIFO_DEPTH - DMATDLR

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer.

Consider the following:

- Transmit FIFO watermark level = DMATDLR = 64: †
- DMA burst length = FIFO_DEPTH - DMATDLR = 192: †
- SPI transmit FIFO_DEPTH = 256: †
- Block transaction size = 960: †

Figure 19-18: Transmit FIFO Watermark Level = 64



The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 960/192 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, `DMATDLR`, is quite low. Therefore, there is a high probability that the SPI serial transmit line will need to transmit data when there is no data left in the transmit FIFO buffer. This is a transmit underflow condition. This occurs because the DMA has not had time to service the DMA request before the FIFO buffer becomes empty.

Example 2: Transmit FIFO Watermark Level = 192

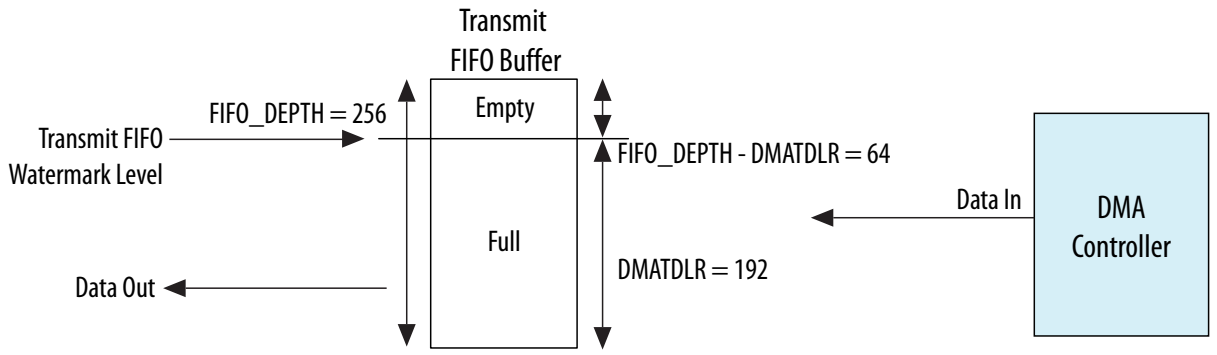
Consider the example where the assumption is made: †

DMA burst length = `FIFO_DEPTH - DMATDLR`

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer. Consider the following:

- Transmit FIFO watermark level = `DMATDLR` = 192 †
- DMA burst length = `FIFO_DEPTH - DMATDLR` = 64 †
- SPI transmit `FIFO_DEPTH` = 256 †
- Block transaction size = 960 †

Figure 19-19: Transmit FIFO Watermark Level = 192



Number of burst transactions in block: †

Block transaction size/DMA burst length = 960/64 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, DMATDLR, is high. Therefore, the probability of SPI transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the SPI transmit FIFO buffer becomes empty. †

This case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case.

Transmit FIFO Buffer Overflow

Setting the DMA transaction burst length to a value greater than the watermark level that triggers the DMA request may cause overflow when there is not enough space in the transmit FIFO buffer to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= FIFO_DEPTH - DMATDLR

In Example 2: Transmit Watermark Level = 192, the amount of space in the transmit FIFO buffer at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO buffer may be full, but not overflowed, at the completion of the burst transaction.

Therefore, for optimal operation, DMA burst length should be set at the FIFO buffer level that triggers a transmit DMA request; that is: †

DMA burst length = FIFO_DEPTH - DMATDLR

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO buffer will not be full at the end of a DMA burst transfer if the SPI controller has successfully transmitted one data item or more on the serial transmit line during the transfer. †

Related Information

Transmit FIFO Watermark on page 19-30

Receive FIFO Buffer Overflow

During SPI serial transfers, receive FIFO buffer requests are made to the DMA whenever the number of entries in the receive FIFO buffer is at or above the DMA Receive Data Level Register, that is DMATDLR + 1.This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO buffer. †

Data should be fetched by the DMA often enough for the receive FIFO buffer to accept serial transfers continuously, that is, when the FIFO buffer begins to fill, another DMA transfer is requested. Otherwise the FIFO buffer will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Choosing Receive Watermark Level

Similar to choosing the transmit watermark level, the receive watermark level, DMATDLR + 1, should be set to minimize the probability of overflow. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Related Information

Texas Instruments Synchronous Serial Protocol (SSP) on page 19-18

Receive FIFO Buffer Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = `DMATDLR` + 1

If the number of data items in the receive FIFO buffer is equal to the source burst length at the time of the burst request is made, the receive FIFO buffer may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, `DMATDLR` + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can improve bus utilization. †

Note: The receive FIFO buffer will not be empty at the end of the source burst transaction if the SPI controller has successfully received one data item or more on the serial receive line during the burst. †

ctrlr0 Fields

Bit	Name	Description	Access	Reset
15:12	cfs	Selects the length of the control word for the Microwire frame format. The length (in bits) is the value of this field plus 1. **Value** — **Description** 0x0 — 1-bit control word 0x1 — 2-bit control word 0x2 — 3-bit control word 0x3 — 4-bit control word 0x4 — 5-bit control word 0x5 — 6-bit control word 0x6 — 7-bit control word 0x7 — 8-bit control word 0x8 — 9-bit control word 0x9 — 10-bit control word 0xA — 11-bit control word 0xB — 12-bit control word 0xC — 13-bit control word 0xD — 14-bit control word 0xE — 15-bit control word 0xF — 16-bit control word	RW	0x0
11	srl	Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. **Value** — **Description** 0x0 — Normal Mode Operation 0x1 — Test Mode Operation	RW	0x0

Bit	Name	Description	Access	Reset
9:8	tmod	Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory. It is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. **Value** — **Description** 0x0 — Transmit & and Receive 0x1 — Transmit Only 0x2 — Receive Only 0x3 — EEPROM Read	RW	0x0
7	scpol	Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the SPI Master is not actively transferring data on the serial bus. **Value** — **Description** 0x0 — Inactive state of serial clock is low 0x1 — Inactive state of serial clock is high	RW	0x0
6	scph	Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. **Value** — **Description** 0x0 — Serial clock toggles in middle of first data bit 0x1 — Serial clock toggles at start of first data bit	RW	0x0

Bit	Name	Description	Access	Reset
5:4	frf	Selects which serial protocol transfers the data. **Value** — **Description** 0x0 — Motorola SPI 0x1 — Texas Instruments SSP 0x2 — National Semi Microwire	RW	0x0
3:0	dfs	Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. **Value** — **Description** 0x3 — 4-bit serial data transfer 0x4 — 5-bit serial data transfer 0x5 — 6-bit serial data transfer 0x6 — 7-bit serial data transfer 0x7 — 8-bit serial data transfer 0x8 — 9-bit serial data transfer 0x9 — 10-bit serial data transfer 0xA — 11-but serial data 0xB — 12-bit serial data 0xC — 13-bit serial data 0xD — 14-bit serial data 0xE — 15-bit serial data 0xF — 16-bit serial data	RW	0x7

ctrlr1

Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the SPI Master is enabled.The SPI Master is enabled and disabled by writing to the SPIENR register.

mwcr Fields

Bit	Name	Description	Access	Reset
2	mhs	Used to enable and disable the busy/ready handshaking interface for the Microwire protocol. When enabled, the SPI Master checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register. **Value** **Description** 0x0 Handshaking interface is disabled 0x1 Handshaking interface is enabled	RW	0x0
1	mdd	Defines the direction of the data word when the Microwire serial protocol is used. **Value** **Description** 0x0 SPI Master receives data 0x1 SPI Master transmits data	RW	0x0
0	mwmod	Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received. **Value** **Description** 0x0 non-sequential transfer 0x1 sequential transfer	RW	0x0

ser

The register enables the individual slave select output lines from the SPI Master. Up to 4 slave-select output pins are available on the SPI Master. You cannot write to this register when SPI Master is busy and when SPI_EN = 1.

Module Instance	Base Address	Register Address

Reserved												ser RW 0x0			

ser Fields

Bit	Name	Description	Access	Reset
3:0	ser	Each bit in this register corresponds to a slave select line (spim_ss_x_n] from the SPI Master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set. **Value** **Description** 0x0 Slave x Not Selected 0x1 Slave x Selected	RW	0x0

baudr

This register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the spi_m_clk divider value. It is impossible to write to this register when the SPI Master is enabled. The SPI Master is enabled and disabled by writing to the SPIENR register.

Module Instance	Base Address	Register Address

sckdv RW 0x0															

baudr Fields

Bit	Name	Description	Access	Reset
15:0	sckdv	The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (spim_sclk_out) is disabled. The frequency of the spim_sclk_out is derived from the following equation: Fspim_sclk_out = Fspi_m_clk/ SCKDV where SCKDV is any even value between 2 and 65534. For example: for Fspi_m_clk = 3.6864MHz and SCKDV =2 Fspim_sclk_out = 3.6864/2 = 1.8432MHz	RW	0x0

txftlr

This register controls the threshold value for the transmit FIFO memory. It is impossible to write to this register when the SPI Master is enabled. The SPI Master is enabled and disabled by writing to the SPIENR register.

dr

This register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SPI_EN = 1. FIFOs are reset when SPI_EN = 0. The data register occupies thirty-six 32-bit locations in the address map (0x60 to 0xec). These are all aliases for the same data register. This is done to support burst accesses. .

Module Instance	Base Address	Register Address
spim0	0xFFF00000	0xFFF00060 to 0xFFF000EC

ctrlr0 Fields

Bit	Name	Description	Access	Reset
15:12	cfs	Selects the length of the control word for the Microwire frame format. The length (in bits) is the value of this field plus 1. **Value** — **Description** 0x0 — 1-bit control word 0x1 — 2-bit control word 0x2 — 3-bit control word 0x3 — 4-bit control word 0x4 — 5-bit control word 0x5 — 6-bit control word 0x6 — 7-bit control word 0x7 — 8-bit control word 0x8 — 9-bit control word 0x9 — 10-bit control word 0xA — 11-bit control word 0xB — 12-bit control word 0xC — 13-bit control word 0xD — 14-bit control word 0xE — 15-bit control word 0xF — 16-bit control word	RW	0x0

Bit	Name	Description	Access	Reset
11	srl	Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. **Value** **Description** 0x0 Normal Mode Operation 0x1 Test Mode Operation	RW	0x0
10	slv_oe	This bit enables or disables the setting of the spis0_ssi_oe_n output from the SPI Slave. When SLV_OE = 1, the spis0_ssi_oe_n output can never be active. When the spis0_ssi_oe_n output controls the tri-state buffer on the txd output from the slave, a high impedance state is always present on the slave spis0_txd output when SLV_OE = 1. This is useful when the master transmits in broadcast mode (master transmits data to all slave devices). Only one slave may respond with data on the master spis0_rxd line. This bit is enabled after reset and must be disabled by software (when broadcast mode is used), if you do not want this device to respond with data. **Value** **Description** 0x0 Slave txd is enabled 0x1 Slave txd is disabled	RW	0x0
9:8	tmod	Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory **Value** **Description** 0x0 Transmit & and Receive 0x1 Transmit Only 0x2 Receive Only	RW	0x0

Bit	Name	Description	Access	Reset
7	scpol	Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the spi master is not actively transferring data on the serial bus. **Value** **Description** 0x0 Inactive state of serial clock is low 0x1 Inactive state of serial clock is high	RW	0x0
6	scph	Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. **Value** **Description** 0x0 Serial clock toggles in middle of first data bit 0x1 Serial clock toggles at start of first data bit	RW	0x0
5:4	frf	Selects which serial protocol transfers the data. **Value** **Description** 0x0 Motorola SPI 0x1 Texas instruments SSP 0x2 National Semi Microwire	RW	0x0

Bit	Name	Description	Access	Reset
3:0	dfs	Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receiver FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. **Value** — **Description** 0x3 — 4-bit serial data transfer 0x4 — 5-bit serial data transfer 0x5 — 6-bit serial data transfer 0x6 — 7-bit serial data transfer 0x7 — 8-bit serial data transfer 0x8 — 9-bit serial data transfer 0x9 — 10-bit serial data transfer 0xA — 11-but serial data 0xB — 12-bit serial data 0xC — 13-bit serial data 0xD — 14-bit serial data 0xE — 15-bit serial data 0xF — 16-bit serial data	RW	0x7

spienr

Enables and disables all SPI operations.

Module Instance	Base Address	Register Address

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO

buffer; a write can occur only when SPI_EN = 1. FIFOs are reset when SPI_EN = 0. Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the RxFIFO onto the bus.

I²C Controller 20

2015.11.02

av_5v4 Subscribe Send Feedback

The I²C controller provides support for a communication link between integrated circuits on a board. It is a simple two-wire bus which consists of a serial data line (SDA) and a serial clock (SCL) for use in applications such as temperature sensors and voltage level translators to EEPROMs, A/D and D/A converters, CODECs, and many types of microprocessors. †

The hard processor system (HPS) provides four I²C controllers to enable system software to communicate serially with I²C buses. Each I²C controller can operate in master or slave mode, and support standard mode of up to 100 Kbps or fast mode of up to 400 Kbps. These I²C controllers are instances of the Synopsys® DesignWare® APB I²C (DW_apb_i2c) controller.

Each I²C controller must be programmed to operate in either master or slave mode only. Operating as a master and slave simultaneously is not supported. † (59)

Features of the I²C Controller

The I²C controller has the following features:

- Maximum clock speed of up to 400 Kbps
- One of the following I²C operations:
  - A master in an I²C system and programmed only as a master †
  - A slave in an I²C system and programmed only as a slave †
- 7- or 10-bit addressing †
- Mixed read and write combined-format transactions in both 7-bit and 10-bit addressing mode †
- Bulk transmit mode †
- Transmit and receive buffers †
- Handles bit and byte waiting at all bus speeds †
- DMA handshaking interface †

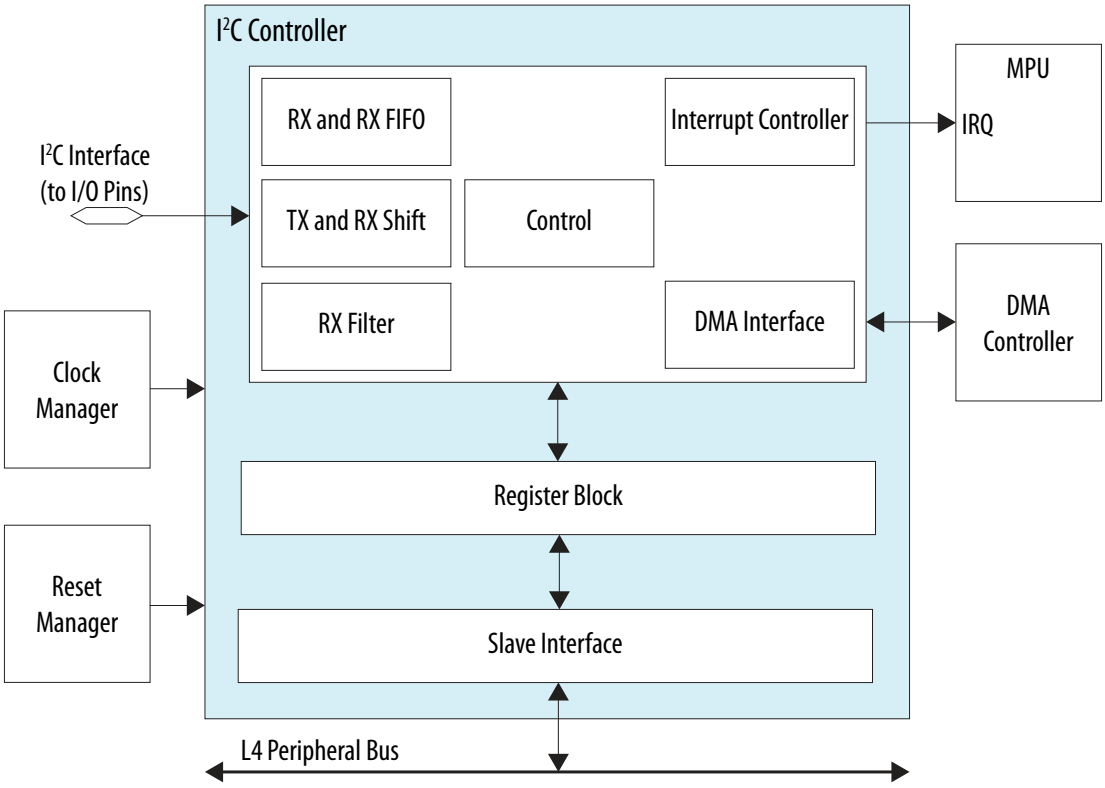
I²C Controller Block Diagram and System Integration

The I²C controller consists of an internal slave interface, an I²C interface, and FIFO logic to buffer data between the two interfaces. †

The host processor accesses data, control, and status information about the I²C controller through a 32-bit slave interface.

Figure 20-1: I²C Controller Block Diagram



The I²C controller consists of the following modules and interfaces:

- Slave interface for control and status register (CSR) accesses and DMA transfers, allowing a master to access the CSRs and the DMA to read or write data directly.
- Two FIFO buffers for transmit and receive data, which hold the Rx FIFO and Tx FIFO buffer register banks and controllers, along with their status levels. †
- Shift logic for parallel-to-serial and serial-to-parallel conversion
  - Rx shift – Receives data into the design and extracts it in byte format. †
  - Tx shift – Presents data supplied by CPU for transfer on the I²C bus. †
- Control logic responsible for implementing the I²C protocol.

- DMA interface that generates handshaking signals to the DMA controller in order to automate the data transfer without CPU intervention. †
- Interrupt controller that generates raw interrupts and interrupt flags, allowing them to be set and cleared. †
- Receive filter for detecting events, such as start and stop conditions, in the bus; for example, start, stop and arbitration lost. †

I²C Controller Signal Description

All instances of the I²C controller connect to external pins through pin multiplexers. Pin multiplexing allows all instances to function simultaneously and independently. The pins must be connected to a pull-up resistors and the I²C bus capacitance cannot exceed 400 pF.

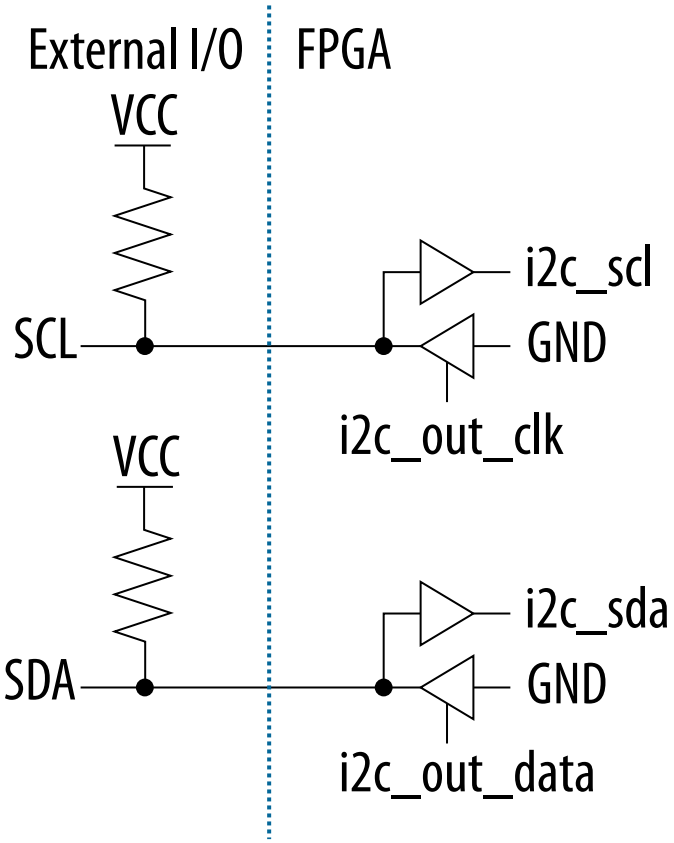
Table 20-1: I²C Controller Interface HPS I/O Pins

Pin Name	Signal Width	Direction	Description
SCL	1 bit	Bidirectional	Serial clock
SDA	1 bit	Bidirectional	Serial data

Table 20-2: HPS I²C Signals for FPGA Routing

Signal Name	Signal Width	Direction	Description
i2c<#>_scl	1 bit	Input	Incoming I²C clock source. This is the input SCL signal
i2c<#>_out_clk	1 bit	Output	Outgoing I²C clock enable. Output SCL signal. This signal is logically inverted and is synchronous to the HPS peripheral clock
i2c<#>_sda	1 bit	Input	Incoming I²C data. This is the input SDA signal.
i2c<#>_out_data	1 bit	Output	Outgoing I²C data enable. Output SDA signal. This signal is logically inverted and is synchronous to the HPS peripheral clock.

Figure 20-2: I²C interface in FPGA fabric



The figure above shows the typical connection on the I²C interface in FPGA fabric with `alt_iobuff`.

For both I2C clock and data, external IO pins are open drain connection. When output enables `i2c_out_data` and `i2c_out_clk` are asserted, external signal will be driven to ground.

Related Information

I/O Buffer (ALTIOBUF)

For more information on configuring open drain I/O buffer to connect I²C signals to external I/O pins, please refer to Altera I/O Buffer (ALTIOBUF) Megafunction User Guide.

Functional Description of the I²C Controller

Feature Usage

The I²C controller can operate in standard mode (with data rates of up to 100 Kbps) or fast mode (with data rates less than or equal to 400 Kbps). Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kbps I²C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I²C bus system as they cannot follow the higher transfer rate and therefore unpredictable states would occur. †

You can attach any I²C controller to an I²C-bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus and there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. †

Behavior

You can control the I²C controller via software to be in either mode:

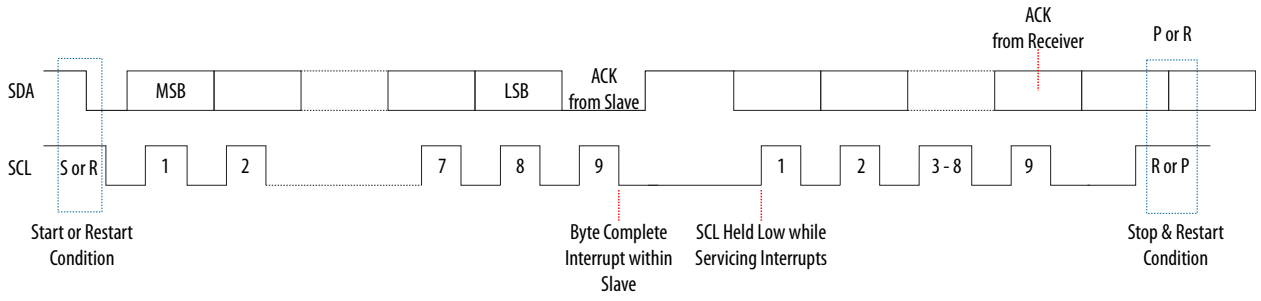
- An I²C master only, communicating with other I²C slaves.
- An I²C slave only, communicating with one or more I²C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I²C protocol also allows multiple masters to reside on the I²C bus and uses an arbitration procedure to determine bus ownership. †

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address. †

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver receives one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with an ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. †

Figure 20-3: Data transfer on the I²C Bus †



The I²C controller is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages. †

START and STOP Generation

When operating as a master, putting data into the transmit FIFO causes the I²C controller to generate a START condition on the I²C bus. In order for the master to complete the transfer and issue a STOP condition it must find a transmit FIFO entry tagged with a stop bit. Allowing the transmit FIFO to empty without a stop bit set, the master will stall the transfer by holding the SCL line low. †

When operating as a slave, the I²C controller does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the I²C controller, it holds the SCL line low until read data has been supplied to it. This stalls the I²C bus until read data is provided to the slave I²C controller, or the I²C controller slave is disabled by writing a 0 to bit 0 of `IC_ENABLE` register. †

Combined Formats

The I²C controller supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. †

The I²C controller does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. †

To initiate combined format transfers, the `IC_RESTART_EN` bit in the `IC_CON` register should be set to 1. With this value set and operating as a master, when the I²C controller completes an I²C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the `IC_RESTART_EN` is 0, a STOP will be issued followed by a START condition. Another way to generate the RESTART condition is to set the Restart bit [10] of the `DATA_CMD` register. Regardless if the direction of the transfer changes or not the RESTART condition will be generated.†

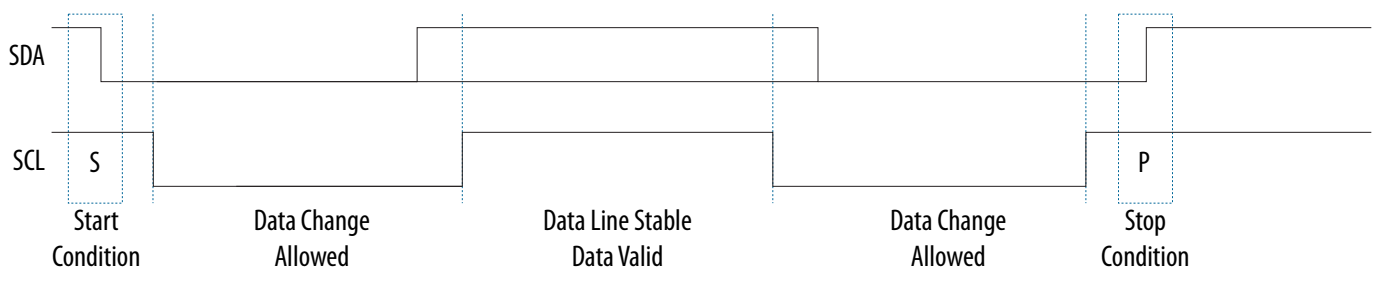
Protocol Details

START and STOP Conditions

When the bus is idle, both the SCL and SDA signals are pulled high through pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the SDA signal while SCL is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the SDA line while SCL is 1. †

The following figure shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the SDA line must be stable when SCL is 1. †

Figure 20-4: Timing Diagram for START and STOP Conditions



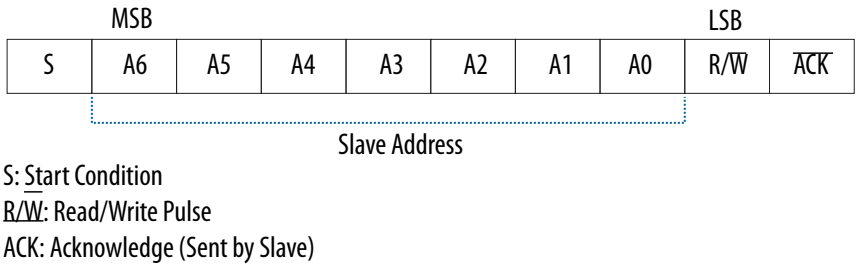
The signal transitions for the START or STOP condition, as shown in the figure, reflect those observed at the output signals of the master driving the I^2C bus. Care should be taken when observing the SDA or SCL signals at the input signals of the slave(s), because unequal line delays may result in an incorrect SDA or SCL timing relationship. †

Addressing Slave Protocol

7-Bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in the following figure. When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave. †

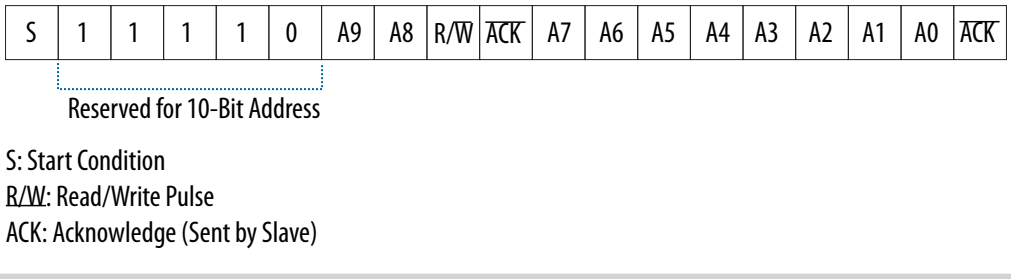
Figure 20-5: 7- Bit Address Format



10-Bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. †

Figure 20-6: 10-Bit Address Format



The following table defines the special purpose and reserved first byte addresses. †

Table 20-3: I^2C Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General call address. The I^2C controller places the data in the receive buffer and issues a general call interrupt.

Slave Address	R/W Bit	Description
0000 000	1	START byte. For more details, refer to "START BYTE Transfer Protocol"
0000 001	X	CBUS address. The I^2C controller ignores these accesses.
0000 010	X	Reserved
0000 011	X	Reserved
0000 1XX	X	Unused
1111 1XX	X	Reserved
1111 0XX	X	10-bit slave addressing.

Note to Table: 'X' indicates do not care.

Related Information

START BYTE Transfer Protocol on page 20-10

Transmitting and Receiving Protocol

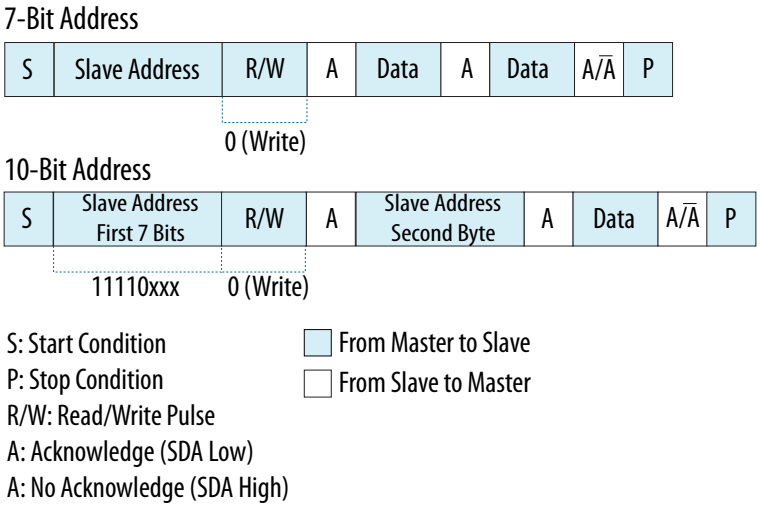
The master can initiate data transmission and reception to or from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to or from the bus, acting as either a slave-transmitter or slave-receiver, respectively. †

Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. †

If the master-transmitter is transmitting data as shown in the following figure, then the slave-receiver responds to the master-transmitter with an ACK pulse after every byte of data is received. †

Figure 20-7: Master-Transmitter Protocol †



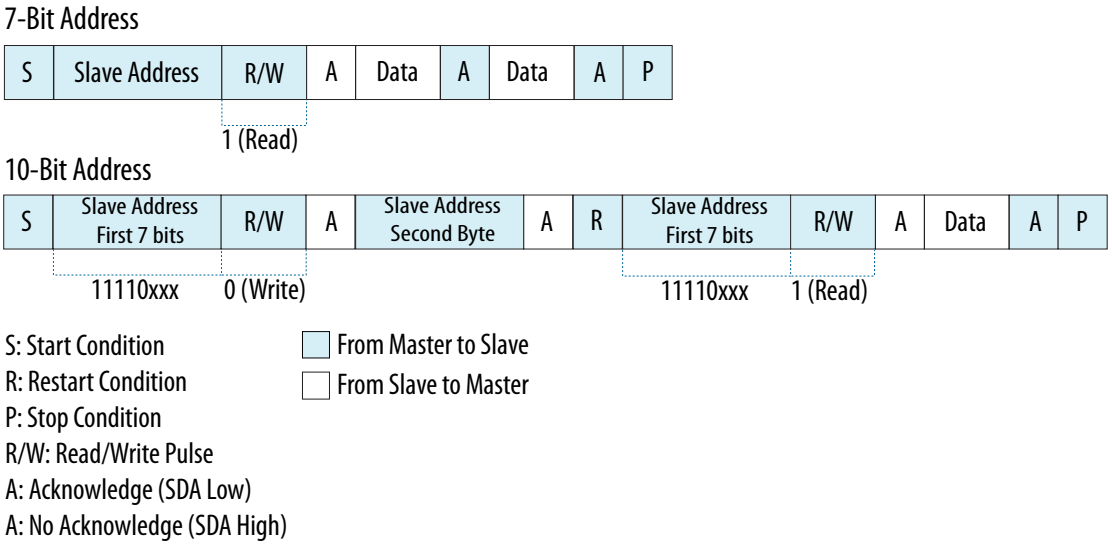
Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in the following figure, then the master responds to the slave-transmitter with an ACK pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) bit so that the master can issue a STOP condition. †

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the I^2C controller can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the I^2C controller supports, refer to "Combined Formats" section of this chapter. †

Note: The I^2C controller must be inactive on the serial port before the target slave address register, `IC_TAR`, can be reprogrammed. †

Figure 20-8: Master-Receiver Protocol †



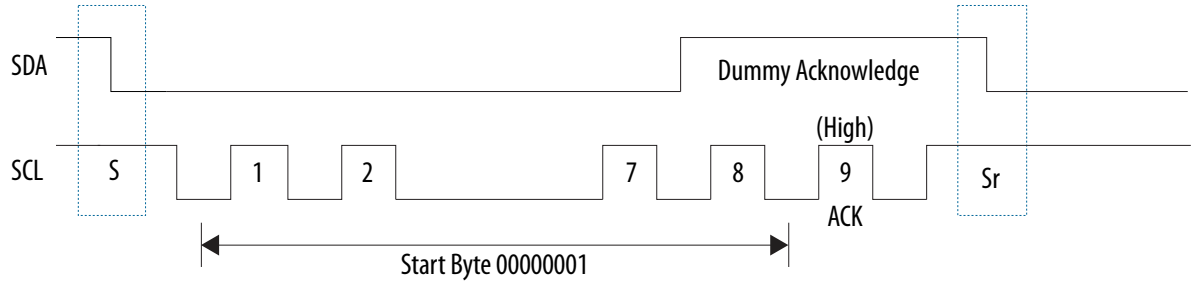
Related Information

Combined Formats on page 20-6

START BYTE Transfer Protocol

The START BYTE transfer protocol is set up for systems that do not have an on-board dedicated I^2C hardware module. When the I^2C controller is set as a slave, it always samples the I^2C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when I^2C controller is set as a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it. This protocol consists of seven zeros being transmitted followed by a 1, as illustrated in the following figure. This allows the processor that is polling the bus to under-sample the address phase until the microcontroller detects a 0. Once the microcontroller detects a 0, it switches from the under sampling rate to the correct rate of the master. †

Figure 20-9: START BYTE Transfer †



The START BYTE has the following procedure: †

1. Master generates a START condition. †
2. Master transmits the START byte (0000 0001). †
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus) †
4. No slave sets the ACK signal to 0. †
5. Master generates a RESTART (R) condition. †

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated. †

Multiple Master Arbitration

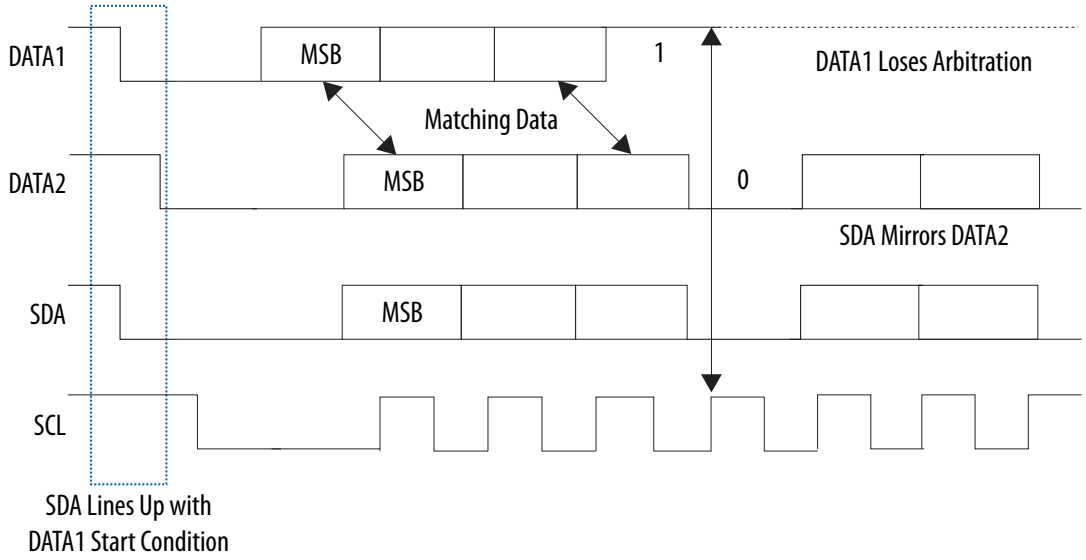
The I^2C controller bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I^2C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by simultaneously generating a START condition. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state. †

Arbitration takes place on the SDA line, while the SCL line is 1. The master, which transmits a 1 while the other master transmits 0, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase. †

Upon detecting that it has lost arbitration to another master, the I^2C controller stops generating SCL. †

The following figure illustrates the timing of two masters arbitrating on the bus.

Figure 20-10: Multiple Master Arbitration †



The bus control is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus. †

Arbitration is not allowed between the following conditions: †

- A RESTART condition and a data bit †
- A STOP condition and a data bit †
- A RESTART condition and a STOP condition †

Slaves are not involved in the arbitration process. †

Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL clock. Clock synchronization is performed using the wired-AND connection to the SCL signal. When the master transitions the SCL clock to 0, the master starts counting the low time of the SCL clock and transitions the SCL clock signal to 1 at the beginning of the next clock period. However, if another master is holding the SCL line to 0, then the master goes into a HIGH wait state until the SCL clock line transitions to 1. †

All masters then count off their high time, and the master with the shortest high time transitions the SCL line to 0. The masters then counts out their low time and the one with the longest low time forces the other master into a HIGH wait state. Therefore, a synchronized SCL clock is generated, which is illustrated in the following figure. Optionally, slaves may hold the SCL line low to slow down the timing on the I^2C bus. †

Figure 20-11: Multiple Master Clock Synchronization †

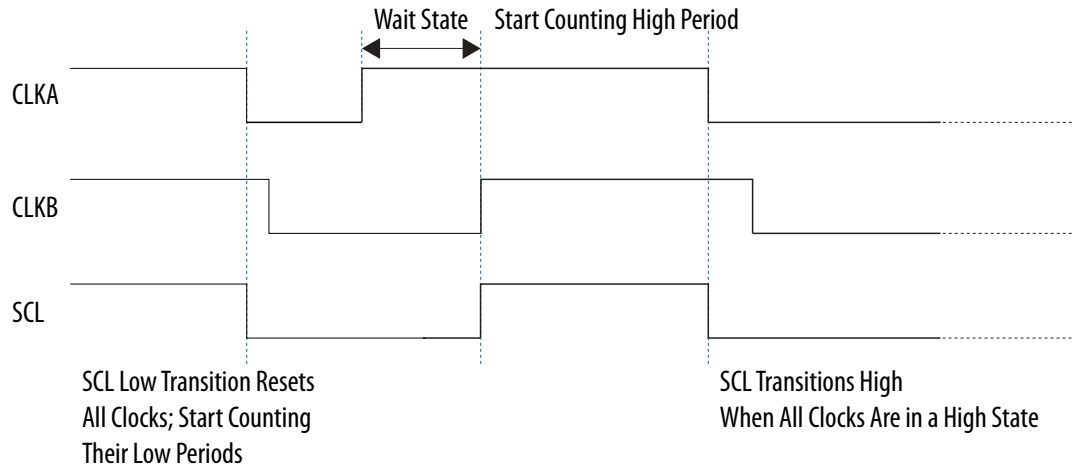


Figure 20-12: Impact of SCL Rise Time and Fall Time on Generated SCL

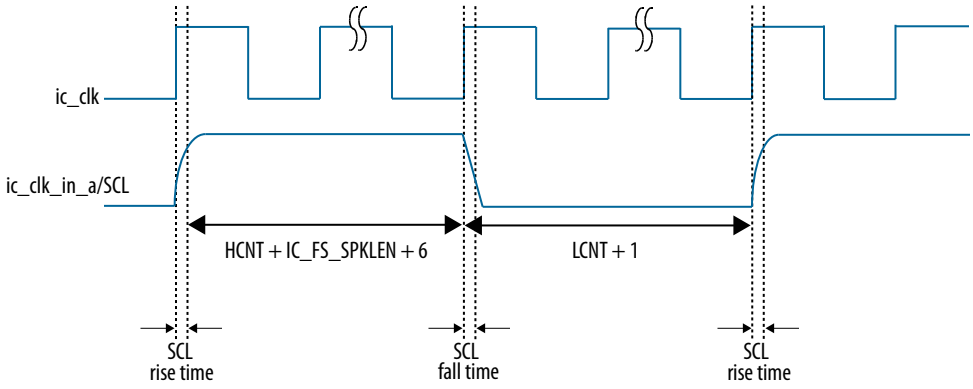


The following equations can be used to compute SCL high and low time:

```
SCL_High_time = [(HCNT + IC_FS_SPKLEN + 6)*ic_clk] + SCL_Fall_time
SCL_Low_time = [(LCNT + 1)*ic_clk] - SCL_Fall_time + SCL_Rise_time
```

Clock Frequency Configuration

When you configure the I²C controller as a master, the SCL count registers must be set before any I²C bus transaction can take place in order to ensure proper I/O timing. † There are four SCL count registers:

- Standard speed I²C clock SCL high count, `IC_SS_SCL_HCNT` †
- Standard speed I²C clock SCL low count, `IC_SS_SCL_LCNT` †
- Fast speed I²C clock SCL high count, `IC_FS_SCL_HCNT` †
- Fast speed I²C clock SCL low count, `IC_FS_SCL_LCNT` †

It is not necessary to program any of the SCL count registers if the I²C controller is enabled to operate only as an I²C slave, since these registers are used only to determine the SCL timing requirements for operation as an I²C master. †

Minimum High and Low Counts

When the I²C controller operates as an I²C master in both transmit and receive transfers, the minimum value that can be programmed in the SCL low count registers is 8 while the minimum value allowed for the SCL high count registers is 6. †

The minimum value of 8 for the low count registers is due to the time required for the I²C controller to drive SDA after a negative edge of SCL. The minimum value of 6 for the high count register is due to the time required for the I²C controller to sample SDA during the high period of SCL. †

The I²C controller adds one cycle to the low count register values in order to generate the low period of the SCL clock.

The I²C controller adds seven cycles to the high count register values in order to generate the high period of the SCL clock. This is due to the following factors: †

- The digital filtering applied to the SCL line incurs a delay of four `l4_sp_clk` cycles. This filtering includes metastability removal and a 2-out-of-3 majority vote processing on SDA and SCL edges. †
- Whenever SCL is driven 1 to 0 by the I²C controller—that is, completing the SCL high time—an internal logic latency of three `l4_sp_clk` cycles incurs. †

Consequently, the minimum SCL low time of which the I²C controller is capable is nine (9) `l4_sp_clk` periods (8+1), while the minimum SCL high time is thirteen (13) `l4_sp_clk` periods (6+1+3+3). †

Note: The `ic_fs_spklen` register must be set before any I²C bus transaction can take place to ensure stable operation. This register sets the duration measured in `ic_clk` cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic.†

Calculating High and Low Counts

The calculations below show an example of how to calculate SCL high and low counts for each speed mode in the I²C controller.

The equation to calculate the proper number of `l4_sp_clk` clock pulses required for setting the proper SCL clocks high and low times is as follows: †

Table 20-4: Equation

IC_HCNT = ceil(MIN_SCL_`HIGHtime`*OSCFREQ)

IC_LCNT = ceil(MIN_SCL_`LOWtime`*OSCFREQ)

MIN_SCL_HIGHtime = minimum high period

MIN_SCL_HIGHtime =

4000 ns for 100 kbps

600 ns for 400 kbps

60 ns for 3.4 Mbs, bus loading = 100pF

160 ns for 3.4 Mbs, bus loading = 400pF

MIN_SCL_LOWtime = minimum low period

MIN_SCL_LOWtime =

4700 ns for 100 kbps

1300 ns for 400 kbps

120 ns for 3.4Mbs, bus loading = 100pF

320 ns for 3.4Mbs, bus loading = 400pF

OSCFREQ = `l4_sp_clk` clock frequency (Hz)

Example 20-1: Calculating High and Low Counts

```
OSCFREQ = 100 MHz
I2Cmode = fast, 400 kbps
MIN_SCL_HIGHtime = 600 ns
```

```
MIN_SCL_LOWtime = 1300 ns

IC_HCNT = ceil(600 ns * 100 MHz) IC_HCNTSCL PERIOD = 60
IC_LCNT = ceil(1300 ns * 100 MHz) IC_LCNTSCL PERIOD = 130
Actual MIN_SCL_HIGHtime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns †
```

SDA Hold Time

The I²C protocol specification requires 300 ns of hold time on the SDA signal in standard and fast speed modes. Board delays on the SCL and SDA signals can mean that the hold time requirement is met at the I²C master, but not at the I²C slave (or vice-versa). As each application encounters differing board delays, the I²C controller contains a software programmable register, `IC_SDA_HOLD`, to enable dynamic adjustment of the SDA hold time. `IC_SDA_HOLD` effects both slave-transmitter and master mode.

DMA Controller Interface

The I²C controller supports DMA signaling to indicate when data is ready to be read or when the transmit FIFO needs data. This support requires 2 DMA channels, one for transmit data and one for receive data. The I²C controller supports both single and burst DMA transfers. System software can choose the DMA burst mode by programming an appropriate value into the threshold registers. The recommended setting of the FIFO threshold register value is half full.

To enable the DMA controller interface on the I²C controller, you must write to the DMA control register (`DMACR`) bits. Writing a 1 into the `TDMAE` bit field of `DMACR` register enables the I²C controller transmit handshaking interface. Writing a 1 into the `RDMAE` bit field of the `DMACR` register enables the I²C controller receive handshaking interface. †

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Clocks

Each I²C controller is connected to the `l4_sp_clk` clock, which clocks transfers in standard and fast mode. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to *Clock Manager* chapter.

Resets

Each I²C controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to *Reset Manager* chapter.

Taking the I²C Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

I²C Controller Programming Model

This section describes the programming model for the I²C controllers based on the two master and slave operation modes. †

Note: Each I²C controller should be set to operate only as an I²C master or as an I²C slave, never set both simultaneously. Ensure that bit 6 (`IC_SLAVE_DISABLE`) and 0 (`IC_MASTER_MODE`) of the `IC_CON` register are never set to 0 and 1, respectively. †

Slave Mode Operation

Initial Configuration

To use the I²C controller as a slave, perform the following steps: †

1. Disable the I²C controller by writing a 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the I²C controller responds. †

   Note: The reset value for the I²C controller slave address is 0x55. If you are using 0x55 as the slave address, you can safely skip this step.
3. Write to the `IC_CON` register to specify which type of addressing is supported (7- or 10-bit by setting bit 3). Enable the I²C controller in slave-only mode by writing a 0 into bit 6 (`IC_SLAVE_DISABLE`) and a 0 to bit 0 (`MASTER_MODE`). †

   Note: Slaves and masters do not have to be programmed with the same type of addressing 7- or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa. †
4. Enable the I²C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †

Slave-Transmitter Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and requests data, the I²C controller acts as a slave-transmitter and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the slave address in the `IC_SAR` register of the I²C controller †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter. †
3. The I²C controller asserts the `RD_REQ` interrupt (bit 5 of the `IC_RAW_INTR_STAT` register) and waits for software to respond. †

   If the `RD_REQ` interrupt has been masked, due to bit 5 of the `IC_INTR_MASK` register (`M_RD_REQ` bit field) being set to 0, then it is recommended that you instruct the CPU to perform periodic reads of the `IC_RAW_INTR_STAT` register. †

- Reads that indicate bit 5 of the IC_RAW_INTR_STAT register (R_RD_REQ bit field) being set to 1 must be treated as the equivalent of the RD_REQ interrupt being asserted. †
- Software must then act to satisfy the I²C transfer. †
- The timing interval used should be in the order of 10 times the fastest SCL clock period the I²C controller can handle. For example, for 400 Kbps, the timing interval is 25 us. †

Note: The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I²C bus.†

4. If there is any data remaining in the TX FIFO before receiving the read request, the I²C controller asserts a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register) to flush the old data from the TX FIFO. †

Note: Because the I²C controller's TX FIFO is forced into a flushed/reset state whenever a TX_ABRT event occurs, it is necessary for software to release the I²C controller from this state by reading the IC_CLR_TX_ABRT register before attempting to write into the TX FIFO. For more information, refer to the C_RAW_INTR_STAT register description in the register map.†

If the TX_ABRT interrupt has been masked, due to of IC_INTR_MASK[6] register (M_TX_ABRT bit field) being set to 0, then it is recommended that the CPU performs periodic reads of the IC_RAW_INTR_STAT register. †

- Reads that indicate bit 6 (R_TX_ABRT) being set to 1 must be treated as the equivalent of the TX_ABRT interrupt being asserted. †
- There is no further action required from software. †
- The timing interval used should be similar to that described in the previous step for the IC_RAW_INTR_STAT[5] register. †

5. Software writes to the DAT bits of the IC_DATA_CMD register with the data to be written and writes a 0 in bit 8.†
6. Software must clear the RD_REQ and TX_ABRT interrupts (bits 5 and 6, respectively) of the IC_RAW_INTR_STAT register before proceeding. †

   If the RD_REQ and/or TX_ABRT interrupts have been masked, then clearing of the IC_RAW_INTR_STAT register will have already been performed when either the R_RD_REQ or R_TX_ABRT bit has been read as 1. †
7. The I²C controller transmits the byte. †
8. The master may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Receiver Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and is sending data, the I²C controller acts as a slave-receiver and the following steps occur:†

1. The other I²C master device initiates an I²C transfer with an address that matches the I²C controller's slave address in the IC_SAR register. †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that the I²C controller is acting as a slave-receiver. †
3. I²C controller receives the transmitted byte and places it in the receive buffer. †

Note: If the RX FIFO is completely filled with data when a byte is pushed, then an overflow occurs and the I²C controller continues with subsequent I²C transfers. Because a NACK is not generated, software must recognize the overflow when indicated by the I²C controller (by the R_RX_OVER bit in the IC_INTR_STAT register) and take appropriate actions to recover from lost

data. Hence, there is a real time constraint on software to service the RX FIFO before the latter overflow as there is no way to reapply pressure to the remote transmitting master. †

4. I²C controller asserts the RX_FULL interrupt (IC_RAW_INTR_STAT[2] register). †

   If the RX_FULL interrupt has been masked, due to setting IC_INTR_MASK[2] register to 0 or setting IC_TX_TL to a value larger than 0, then it is recommended that the CPU does periodic reads of the IC_STATUS register. Reads of the IC_STATUS register, with bit 3 (RFNE) set at 1, must then be treated by software as the equivalent of the RX_FULL interrupt being asserted. †
5. Software may read the byte from the IC_DATA_CMD register (bits 7:0). †
6. The other master device may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Transfer Operation for Bulk Transfers

In the standard I²C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (RD_REQ) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. The I²C controller is designed to handle more data in the TX FIFO so that subsequent read requests can receive that data without raising an interrupt to request more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. †

This mode only occurs when I²C controller is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the I²C controller raises the read request interrupt (RD_REQ) and waits for data to be written into the TX FIFO before it can be sent to the remote master. †

If the RD_REQ interrupt is masked, due to bit 5 (M_RD_REQ) of the IC_INTR_STAT register being set to 0, then it is recommended that the CPU does periodic reads of the IC_RAW_INTR_STAT register. Reads of IC_RAW_INTR_STAT that return bit 5 (R_RD_REQ) set to 1 must be treated as the equivalent of the RD_REQ interrupt referred to in this section.†

The RD_REQ interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write 1 byte or more than 1 byte into the TX FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte then the slave must raise the RD_REQ again because the master is requesting for more data. †

If the programmer knows in advance that the remote master is requesting a packet of n bytes, then when another master addresses the I²C controller and requests data, the TX FIFO could be written with n number bytes and the remote master receives it as a continuous stream of data. For example, the I²C controller slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the TX FIFO. There is no need to issue RD_REQ again. †

If the remote master is to receive n bytes from the I²C controller but the programmer wrote a number of bytes larger than n to the TX FIFO, then when the slave finishes sending the requested n bytes, it clears the TX FIFO and ignores any excess bytes. †

The I²C controller generates a transmit abort (TX_ABRT) event to indicate the clearing of the TX FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO are cleared at that time. †

Master Mode Operation

Initial Configuration

For master mode operation, the target address and address format can be changed dynamically without having to disable the I²C controller. This feature is only applicable when the I²C controller is acting as a master because the slave requires the component to be disabled before any changes can be made to the address. To use the I²C controller as a master, perform the following steps: †

For multiple I²C transfers, perform additional writes to the Tx FIFO such that the Tx FIFO does not become empty during the I²C transaction. IF the Tx FIFO is completely emptied at any stage, then the master stalls the transfer by holding the SCL line low because there was no stop bit indicating the master to issue a STOP. The master will complete the transfer when it finds a Tx FIFO entry tagged with a Stop bit.

1. Disable the I²C controller by writing 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_CON` register to set the maximum speed mode supported for slave operation (bits 2:1) and to specify whether the I²C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (bit 3). †
3. Write to the `IC_TAR` register the address of the I²C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I²C. The desired speed of the I²C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the `IC_10BITADDR_MASTER` bit field (bit 12). †
4. Enable the I²C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †
5. Now write the transfer direction and data to be sent to the `IC_DATA_CMD` register. If the `IC_DATA_CMD` register is written before the I²C controller is enabled, the data and commands are lost as the buffers are kept cleared when the I²C controller is not enabled. †

Dynamic IC_TAR or IC_10BITADDR_MASTER Update

The I²C controller supports dynamic updating of the `IC_TAR` (bits 9:0) and `IC_10BITADDR_MASTER` (bit 12) bit fields of the `IC_TAR` register. You can dynamically write to the `IC_TAR` register provided the following conditions are met: †

- The I²C controller is not enabled (`IC_ENABLE`=0); †
- The I²C controller is enabled (`IC_ENABLE`=1); AND I²C controller is NOT engaged in any Master (TX, RX) operation (`IC_STATUS[5]`=0); AND I²C controller is enabled to operate in Master mode (`IC_CON[0]`=1); AND there are no entries in the TX FIFO (`IC_STATUS[2]`=1) †

Master Transmit and Master Receive

The I²C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I²C Rx/Tx Data Buffer and Command Register (`IC_DATA_CMD`). The CMD bit [8] should be written to 0 for I²C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the `IC_DATA_CMD` register, and a 1 should be written to the CMD bit.†

Disabling the I²C Controller

The register IC_ENABLE_STATUS is added to allow software to unambiguously determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. †

1. Define a timer interval (ti2c_poll) equal to the 10 times the signaling period for the highest I²C transfer speed used in the system and supported by the I²C controller. For example, if the highest I²C transfer mode is 400 Kbps, then ti2c_poll is 25 us. †
2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. †
3. Execute a blocking thread/process/function that prevents any further I²C master transactions to be started by software, but allows any pending transfers to be completed.
   - This step can be ignored if the I²C controller is programmed to operate as an I²C slave only. †
4. The variable POLL_COUNT is initialized to zero. †
5. Set IC_ENABLE to 0. †
6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_T_POLL_COUNT, exit with the relevant error code. †
7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. †

DMA Controller Operation

To enable the DMA controller interface on the I²C controller, you must write the DMA Control Register (IC_DMA_CR). Writing a 1 to the TDMAE bit field of IC_DMA_CR register enables the I²C controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the IC_DMA_CR register enables the I²C controller receive handshaking interface.†

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the I²C controller is 64 entries.

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit FIFO Underflow

During I²C serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the value in DMA Transmit Data Level Register (IC_DMA_TDLR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of the data (underflow) causing the maser to stall the transfer by holding the SCL line low. To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit Watermark Level

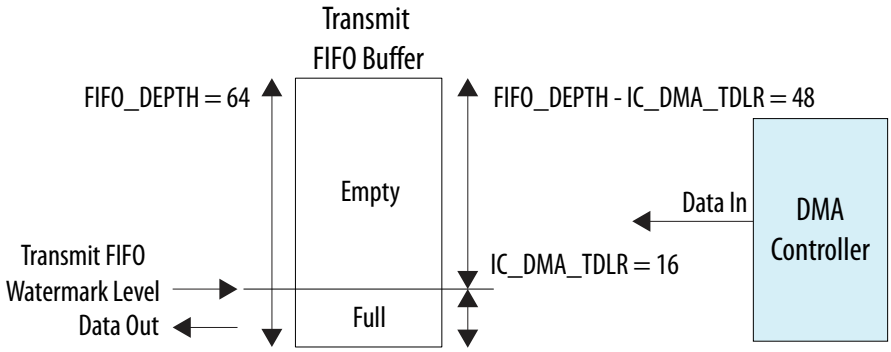
Consider the example where the assumption is made: †

DMA burst length = FIFO_DEPTH - IC_DMA_TDLR †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

- Case 1: IC_DMA_TDLR = 16: †
  - Transmit FIFO watermark level = IC_DMA_TDLR = 16: †
  - DMA burst length = FIFO_DEPTH - IC_DMA_TDLR = 48: †
  - I²C transmit FIFO_DEPTH = 64: †
  - Block transaction size = 240: †

Figure 20-13: Transmit FIFO Watermark Level = 16



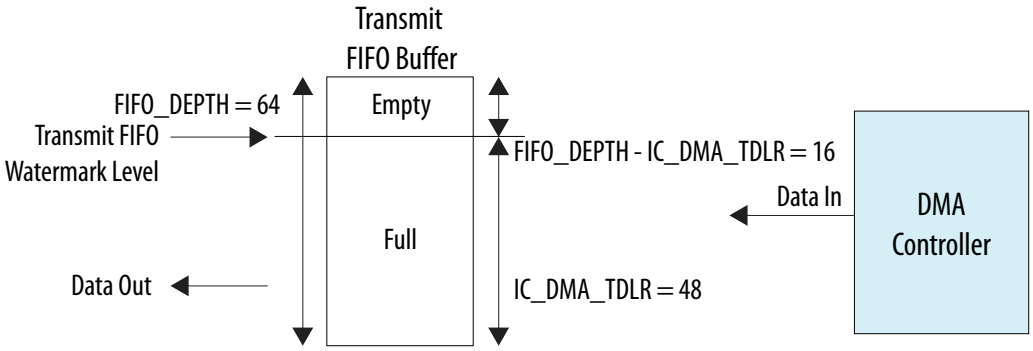
The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 240/48 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, IC_DMA_TDLR, is quite low. Therefore, the probability of transmit underflow is high where the I²C serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

- Case 2: IC_DMA_TDLR = 48 †
  - Transmit FIFO watermark level = IC_DMA_TDLR = 48 †
  - DMA burst length = FIFO_DEPTH - IC_DMA_TDLR = 16 †
  - I²C transmit FIFO_DEPTH = 64 †
  - Block transaction size = 240 †

Figure 20-14: Transmit FIFO Watermark Level = 48



Number of burst transactions in block: †

Block transaction size/DMA burst length = 240/16 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, `IC_ DMA_TDLR`, is high. Therefore, the probability of I^2C transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the I^2C transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the I^2C transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= `FIFO_DEPTH - IC_DMA_TDLR`

In case 2: `IC_DMA_TDLR` = 48, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = `FIFO_DEPTH - IC_DMA_TDLR`

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the I^2C controller has successfully transmitted one data item or more on the I^2C serial transmit line during the transfer. †

Receive FIFO Overflow

During I^2C serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the DMA Receive Data Level Register, that is `IC_DMA_RDLR` + 1. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, `IC_DMA_RDLR` + 1, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

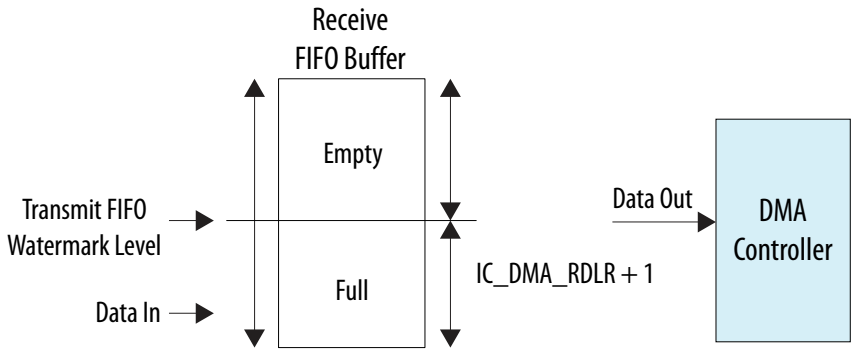
DMA burst length = `IC_DMA_RDLR` + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, `IC_DMA_RDLR` + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

Note: The receive FIFO will not be empty at the end of the source burst transaction if the I^2C controller has successfully received one data item or more on the I^2C serial receive line during the burst. †

Figure 20-15: Receive FIFO Buffer



I2C Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- I2C Module 0
- I2C Module 1
- I2C Module 2
- I2C Module 3

ic_con Fields

Bit	Name	Description	Access	Reset
6	ic_slave_disable	This bit controls whether I2C has its slave disabled. The slave will be disabled, after reset. NOTE: Software should ensure that if this bit is written with 0, then bit [0] of this register should also be written with a 0. **Value** — **Description** 0x1 — slave disable 0x0 — slave enable	RW	0x1
5	ic_restart_en	Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several I2C operations. When RESTART is disabled, the master is prohibited from performing the following functions - Changing direction within a transfer (split), - Sending a START BYTE, - High-speed mode operation, - Combined format transfers in 7-bit addressing modes, - Read operation with a 10-bit address, - Sending multiple bytes per transfer, By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple I2C transfers. If the above operations are performed, it will result in setting bit [6](tx_abort) of the Raw Interrupt Status Register. **Value** — **Description** 0x0 — restart master disable 0x1 — restart master enable	RW	0x1

Bit	Name	Description	Access	Reset
4	ic_10bitaddr_master	This bit controls whether the I2C starts its transfers in 7-or 10-bit addressing mode when acting as a master. **Value** **Description** 0x0 7-bit addressing 0x1 10-bit addressing	RW	0x1
3	ic_10bitaddr_slave	When acting as a slave, this bit controls whether the I2C responds to 7- or 10-bit addresses. In 7-bit addressing, only the lower 7 bits of the Slave Address Register are compared. The I2C responds will only respond to 10-bit addressing transfers that match the full 10 bits of the Slave Address register. **Value** **Description** 0x0 7-bit addressing 0x1 10-bit addressing	RW	0x1
2:1	speed	These bits control at which speed the I2C operates, its setting is relevant only if one is operating the I2C in master mode. Hardware protects against illegal values being programmed by software. This field should be programmed only with standard or fast speed. **Value** **Description** 0x1 standard mode (100 kbit/s) 0x2 fast mode (400 kbit/s)	RW	0x2
0	master_mode	This bit controls whether the i2c master is enabled. NOTE: Software should ensure that if this bit is written with '1', then bit 6 should also be written with a '1'. **Value** **Description** 0x0 master disabled 0x1 master enabled	RW	0x1

ic_tar

This register can be written to only when the ic_enable register is set to 0. This register is 13 bits wide. All bits can be dynamically updated as long as any set of the following conditions are true, (Enable Register bit 0 is set to 0) or (Enable Register bit 0 is set to 1 AND (I2C is NOT engaged in any Master [tx, rx] operation [ic_status register mst_activity bit 5 is set to 0]) AND (I2C is enabled to operate in Master mode[ic_con bit[0] is set to one]) AND (there are NO entries in the TX FIFO Register [IC_STATUS bit [2] is set to 1])

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC04004
i2c1	0xFFC05000	0xFFC05004
i2c2	0xFFC06000	0xFFC06004
i2c3	0xFFC07000	0xFFC07004

Offset: 0x4

ic_tar Fields

Bit	Name	Description	Access	Reset
12	ic_10bitaddr_master	This bit controls whether the i2c starts its transfers in 7-bit or 10-bit addressing mode when acting as a master. **Value** — **Description** 0x0 — Master Address, 7bit 0x1 — Master Address, 10bit	RW	0x1
11	special	This bit indicates whether software performs a General Call or START BYTE command. **Value** — **Description** 0x0 — Ignore bit 10 gc_or_start and use ic_tar normally 0x1 — Perform special I2C command as specified in gc_or_start	RW	0x0

Bit	Name	Description	Access	Reset
10	gc_or_start	If bit 11 (SPECIAL) of this Register is set to 1, then this bit indicates whether a General Call or START byte command is to be performed by the I2C or General Call Address after issuing a General Call, only writes may be performed. Attempting to issue a read command results in setting bit 6 (TX_ABRT) of the Raw Interrupt_Status register. The I2C remains in General Call mode until the special bit value (bit 11) is cleared. **Value** **Description** 0x0 General Call 0x1 START Byte	RW	0x0
9:0	ic_tar	This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits. If the ic_tar and ic_sar are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.	RW	0x55

ic_sar

ic_sar Fields

Bit	Name	Description	Access	Reset
9:0	ic_sar	The Slave Address register holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only Field Bits [6:0] of the Slave Address Register are used. This register can be written only when the I2C interface is disabled, which corresponds to field bit 0 of the Enable Register being set to 0. Writes at other times have no effect. Note, the default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the Slave Address Register or Target Address Register to a reserved value.	RW	0x55

ic_data_cmd

This is the register the CPU writes to when filling the TX FIFO. Reading from this register returns bytes from RX FIFO.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC04010
i2c1	0xFFC05000	0xFFC05010
i2c2	0xFFC06000	0xFFC06010

Reserved					restart WO 0x0	stop WO 0x0	cmd WO 0x0	dat RW 0x0							

ic_data_cmd Fields

Bit	Name	Description	Access	Reset
10	restart	This bit controls whether a RESTART is issued before the byte is sent or received. 1 = A RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command. 0 = A RESTART is issued only if the transfer direction is changing from the previous command. **Value** **Description** 0x1 Issue Restart 0x0 Issue Restart On Direction Change	WO	0x0
9	stop	This bit controls whether a STOP is issued after the byte is sent or received. 1 = STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. 0 = STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. **Value** **Description** 0x1 Issue Stop 0x0 Do Not Issue Stop	WO	0x0

Bit	Name	Description	Access	Reset
8	cmd	This bit controls whether a read or a write is performed. This bit does not control the direction when the I2C acts as a slave. It controls only the direction when it acts as a master. When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that the CPU data is to be transmitted. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a tx_abrt interrupt (bit 6 of the Raw Intr Status Register), unless bit 11 special in the Target Address Register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a tx_abrt interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer on I2C, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing I2C. In this type of scenario, I2C ignores the Data Cmd write, generates a tx_abrt interrupt, and waits to service the RD_REQ interrupt. **Value** **Description** 0x1 Master Read 0x0 Master Write	WO	0x0
7:0	dat	This Field contains the data to be transmitted or received on the I2C bus. If you are writing to these bits and want to perform a read, bits 7:0 (dat) are ignored by the I2C. However, when you read from this register, these bits return the value of data received on the I2C interface.	RW	0x0

ic_ss_scl_hcnt

This register sets the SCL clock high-period count for standard speed.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC04014
i2c1	0xFFC05000	0xFFC05014

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RO	0x0
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
9	r_stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
8	r_activity	This bit captures I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C - Reading the ic_clr_activity register - Reading the ic_clr_intr register - I2C reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RO	0x0
7	r_rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RO	0x0
6	r_tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'.When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0

Bit	Name	Description	Access	Reset
5	r_rd_req	This bit is set to 1 when i2c is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0
4	r_tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, this bit is set to 0.	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the Data and Command Register. When the module is disabled, this bit keeps its level until the master or slave state machines goes into idle, then interrupt is cleared.	RO	0x0
2	r_rx_full	Set when the receive buffer reaches or goes above the Receive FIFO Threshold Value(rx_tl). It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled, Bit [0] of the Enable Register set to 0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the Enable Register Bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0
1	r_rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled, Enable Register bit[0] is set to 0 this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

Bit	Name	Description	Access	Reset
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the Tx Rx Data and Command Register. If the module is disabled, Enable Register is set to 0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

ic_intr_mask

These bits mask their corresponding interrupt status bits.

Module Instance	Base Address	Register Address

ic_intr_mask Fields

Bit	Name	Description	Access	Reset
11	m_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RW	0x1
10	m_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RW	0x0
9	m_stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether i2c is operating in slave or master mode.	RW	0x0

Bit	Name	Description	Access	Reset
8	m_activity	This bit captures i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the i2c - Reading the ic_clr_activity register - Reading the ic_clr_intr register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RW	0x0
7	m_rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RW	0x1
6	m_tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RW	0x1
5	m_rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_ req register.	RW	0x1
4	m_tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_ enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	RW	0x1

Bit	Name	Description	Access	Reset
3	m_tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RW	0x1
2	m_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	RW	0x1
1	m_rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RW	0x1
0	m_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, and then this interrupt is cleared.	RW	0x1

ic_raw_intr_stat

Unlike the ic_intr_stat register, these bits are not masked so they always show the true status of the I2C.

Module Instance	Base Address	Register Address

ic_raw_intr_stat Fields

Bit	Name	Description	Access	Reset
11	gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RO	0x0
10	start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
9	stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
8	activity	This bit captures i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C - Reading the ic_clr_activity register - Reading the ic_clr_intr register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the i2c module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RO	0x0
7	rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RO	0x0

Bit	Name	Description	Access	Reset
6	tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0
5	rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The i2c holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0
4	tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the IC_ ENABLE bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_ enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0

Bit	Name	Description	Access	Reset
1	rx_over	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0), this bit keeps its level until the master or slave state machines go into then, this interrupt is cleared.	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

ic_rx_tl

I2C Receive FIFO Threshold Register.

Module Instance	Base Address	Register Address

Reserved								rx_tl RW 0x0							

ic_rx_tl Fields

Bit	Name	Description	Access	Reset
7:0	rx_tl	Controls the level of entries (or above) that triggers the RX_FULL interrupt (bit 2 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that hardware does not allow this value to be set to a value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 1 entry, and a value of 255 sets the threshold for 256 entries.	RW	0x0

ic_tx_tl

Sets FIFO depth for Interrupt.

ic_enable Fields

Bit	Name	Description	Access	Reset
1	txabort	Write 1 does a TX abort. Self cleared on abort completion	RW	0x0

Bit	Name	Description	Access	Reset
0	enable	Controls whether the I2C is enabled. Software can disable I2C while it is active. However, it is important that care be taken to ensure that I2C is disabled properly. When the I2C is disabled, the following occurs: The TX FIFO and RX FIFO get flushed. Status bits in the IC_INTR_STAT register are still active until I2C goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the I2C stops the current transfer at the end of the current byte and does not acknowledge the transfer. The l4_sp_clk synchronizes pclk and ic_clk. The register ic_enable_ status is added to allow software to determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. Only one register is required to be monitored. Procedure for Disabling I2C 1. Define a timer interval (ti2c_ poll) equal to the 10 times the signaling period for the highest I2C transfer speed used in the system and supported by I2C. For example, if the highest I2C transfer mode is 400 kb/s, then this ti2c_poll is 25us. 2. Define a maximum time-out parameter, MAX_T_ POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. 3. Execute a blocking thread/process/ function that prevents any further I2C master transactions to be started by software, but allows any pending transfers to be completed. 4. The variable POLL_COUNT is initialized to zero. 5. Set IC_ ENABLE to 0. 6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_ T_POLL_COUNT, exit with the relevant error code. 7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. **Value** — **Description** 0x0 — Disables i2c. TX and RX FIFOs are held in an erased state 0x1 — Enables i2c. Software can disable i2c while it is active	RW	0x0

ic_status

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.When the I2C is disabled by writing 0 in bit 0 of the ic_enable register: - Bits 1 and 2 are set to 1 - Bits 3 and 4 are set to 0 When the master or slave state machines goes to idle - Bits 5 and 6 are set to 0

ic_tx_abrt_source

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the ic_clr_tx_abrt register or the ic_clr_intr register is read. To clear Bit 9, the source of the abrt_sbyte_norstrt must be fixed first; RESTART must be enabled (ic_con[5]=1), the special bit must be cleared (ic_tar[11]), or the gc_or_start bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
15	abrt_slvrd_intx	When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Role of I2C: Slave-Transmitter	RW	0x0
14	abrt_slv_arblost	Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then i2c no longer own the bus. Role of I2C: Slave-Transmitter	RW	0x0
13	abrt_slvflush_txfifo	Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Role of I2C: Slave-Transmitter	RW	0x0
12	arb_lost	Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Note: I2C can be both master and slave at the same time. Role of i2c: Master-Transmitter or Slave-Transmitter	RW	0x0
11	abrt_master_dis	User tries to initiate a Master operation with the Master mode disabled. Role of I2C: Master-Transmitter or Master-Receiver	RW	0x0
10	abrt_10b_rd_norstrt	The restart is disabled (ic_restart_en bit (ic_con[5]) =0) and the master sends a read command in 10-bit addressing mode. Role of I2C: Master-Receiver	RW	0x0

Bit	Name	Description	Access	Reset
9	abrt_sbyte_norstrt	To clear Bit 9, the source of then abrt_sbyte_norstrt must be fixed first; restart must be enabled (ic_con[5]=1), the SPECIAL bit must be cleared (ic_tar[11]), or the GC_OR_START bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (ic_con[5]) =0) and the user is trying to send a START Byte. Role of I2C: Master	RW	0x0
8	abrt_hs_norstrt	The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
7	abrt_sbyte_ackdet	Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
6	abrt_hs_ackdet	Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
5	abrt_gcall_read	i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Role of i2c: Master-Transmitter	RW	0x0
4	abrt_gcall_noack	i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call. Role of i2c: Master-Transmitter	RW	0x0
3	abrt_txdata_noack	This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Role of i2c: Master-Transmitter	RW	0x0
2	abrt_10addr2_noack	Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
1	abrt_10addr1_noack	Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0

Bit	Name	Description	Access	Reset
0	abrt_7b_addr_noack	Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0

ic_slv_data_nack_only

The register is used to generate a NACK for the data part of a transfer when i2c is acting as a slave-receiver.

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmardl	This bit field controls the level at which a DMA request is made by the receive logic. The watermark level \= DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when or more data entries are present in the receive FIFO.	RW	0x0

ic_sda_setup

This register controls the amount of time delay (in terms of number of l4_sp_clk clock periods) introduced in the rising edge of SCL relative to SDA changing by holding SCL low when I2C services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. Note: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (l4_sp_clk)], so if the user requires 10 l4_sp_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the I2C when operating as a slave transmitter.

Module Instance	Base Address	Register Address
i2c0	0xFFC04000	0xFFC04094

0	ack_gen_call	When an ACK is asserted, (by asserting i2c_out_data) when it receives a General call. Otherwise, i2c responds with a NACK (by negating i2c_out_data). **Value** **Description** 0x0 I2C responds with a NACK 0x1 I2C responds with an ACK	RW	0x1

ic_enable_status

This register is used to report the i2c hardware status when the IC_ENABLE register is set from 1 to 0; that is, when i2c is disabled. If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE has been set to 0, bits 2:1 are only valid as soon as bit 0 is read as '0'. Note: When ic_enable has been written with '0' a delay occurs for bit 0 to be read as '0' because disabling the i2c depends on I2C bus activities.

Module Instance	Base Address	Register Address

Reserved													slv_rx_data_lost RO 0x0	slv_disabled_while_busy RO 0x0	ic_en RO 0x0

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	slv_rx_data_lost	This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting of IC ENABLE from 1 to 0. When read as 1, i2c is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and ic_enable has been set to 0, then this bit is also set to 1. When read as 0, i2c is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0

Bit	Name	Description	Access	Reset
1	slv_disabled_while_busy	This bit indicates if a potential or active Slave operation has been aborted due to the setting of the ic_enable register from 1 to 0. This bit is set when the CPU writes a 0 to the ic_enable register while: (a) I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, I2C is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in i2c (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and IC_ENABLE has been set to 0, then this bit will also be set to 1. When read as 0, i2c is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0
0	ic_en	This bit always reflects the value driven on the output port ic_en. Not used in current application. When read as 1, i2c is deemed to be in an enabled state. When read as 0, i2c is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read slv_rx_data_lost (bit 2) and slv_disabled_while_busy (bit 1).	RO	0x0

ic_fs_spklen

This register is used to store the duration, measured in ic_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS or FS modes.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
7:0	spklen	This register must be set before any I2C bus transaction can take place to ensure stable operation. This register sets the duration, measured in ic_clk cycles, of the longest spike in the SCL or SDA lines that are filtered out by the spike suppression logic. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 2 being set.	RW	0x2

UART Controller 21

2015.11.02

av_5v4

Subscribe Send Feedback

The hard processor system (HPS) provides two UART controllers for asynchronous serial communication. The UART controllers are based on an industry standard 16550 UART controller. The UART controllers are instances of the Synopsys® DesignWare® APB Universal Asynchronous Receiver/Transmitter (DW_apb_uart) peripheral.(60)

UART Controller Features

The UART controller provides the following functionality and features:

- Programmable character properties, such as number of data bits per character, optional parity bits, and number of stop bits †
- Line break generation and detection †
- Direct memory access (DMA) controller interface
- Prioritized interrupt identification †
- Programmable baud rate
- False start bit detection †
- Automatic flow control mode per 16750 standard †
- Internal loopback mode support
- 128-byte transmit and receive FIFO buffers
  - FIFO buffer status registers †
  - FIFO buffer access mode (for FIFO buffer testing) enables write of receive FIFO buffer by master and read of transmit FIFO buffer by master †
- Shadow registers reduce software overhead and provide programmable reset †
- Transmitter holding register empty (THRE) interrupt mode †

UART Controller Block Diagram and System Integration

Figure 21-1: UART Block Diagram

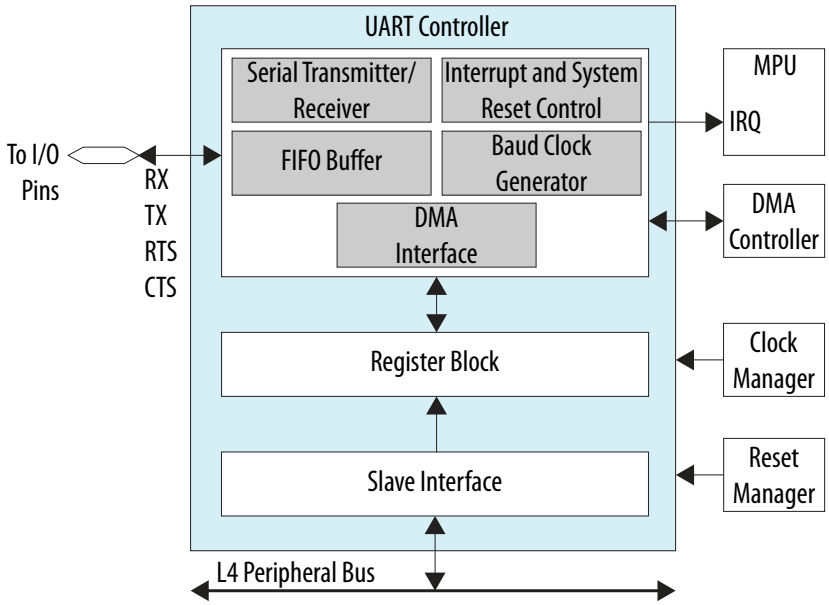

Table 21-1: UART Controller Block Descriptions

Block	Description
Slave interface	Slave interface between the component and L4 peripheral bus.
Register block	Provides main UART control, status, and interrupt generation functions.†
FIFO buffer	Provides FIFO buffer control and storage. †
Baud clock generator	Generates the transmitter and receiver baud clock. With a reference clock of 100 MHz, the UART controller supports transfer rates of 95 baud to 6.25 Mbaud. This supports communication with all known 16550 devices. The baud rate is controlled by programming the interrupt enable or divisor latch high (`IER_DLH`) and receive buffer, transmit holding, or divisor latch low (`RBR_THR_DLL`) registers.

Block	Description
Serial transmitter	Converts parallel data written to the UART into serial data and adds all additional bits, as specified by the control register, for transmission. This makeup of serial data, referred to as a character, exits the block in serial UART. †
Serial receiver	Converts the serial data character (as specified by the control register) received in the UART format to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block. †
DMA interface	The UART controller includes a DMA controller interface to indicate when received data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports single and burst transfers. You can use DMA in FIFO buffer and non-FIFO buffer mode.

Functional Description of the UART Controller

The HPS UART is based on an industry-standard 16550 UART. The UART supports serial communication with a peripheral, modem (data carrier equipment), or data set. The master (CPU) writes data over the slave bus to the UART. The UART converts the data to serial format and transmits to the destination device. The UART also receives serial data and stores it for the master (CPU). †

The UART's registers control the character length, baud rate, parity generation and checking, and interrupt generation. The UART's single interrupt output signal is supported by several prioritized interrupt types that trigger assertion. You can separately enable or disable each of the interrupt types with the control registers. †

FIFO Buffer Support

The UART controller includes 128-byte FIFO buffers to buffer transmit and receive data. FIFO buffer access mode allows the master to write the receive FIFO buffer and to read the transmit FIFO buffer for test purposes. FIFO buffer access mode is enabled with the FIFO access register (FAR). Once enabled, the control portions of the transmit and receive FIFO buffers are reset and the FIFO buffers are treated as empty. †

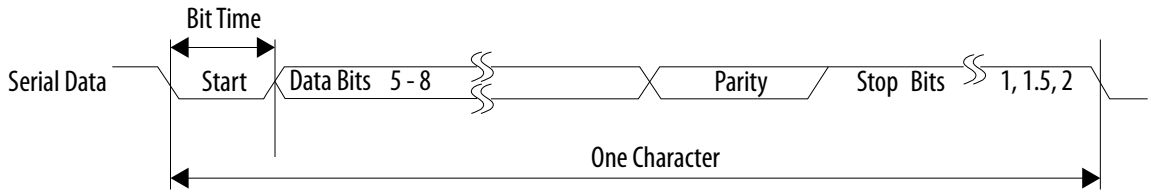
When FIFO buffer access mode is enabled, you can write data to the transmit FIFO buffer as normal; however, no serial transmission occurs in this mode and no data leaves the FIFO buffer. You can read back the data that is written to the transmit FIFO buffer with the transmit FIFO read (TFR) register. The TFR register provides the current data at the top of the transmit FIFO buffer. †

Similarly, you can also read data from the receive FIFO buffer in FIFO buffer access mode. Since the normal operation of the UART is halted in this mode, you must write data to the receive FIFO buffer to read it back. The receive FIFO write (RFW) register writes data to the receive FIFO buffer. The upper two bits of the 10-bit register write framing errors and parity error detection information to the receive FIFO buffer. Bit 9 of RFW indicates a framing error and bit 8 of RFW indicates a parity error. Although you cannot read these bits back from the receive buffer register, you can check the bits by reading the line status register (LSR), and by checking the corresponding bits when the data in question is at the top of the receive FIFO buffer. †

UART(RS232) Serial Protocol

Because the serial communication between the UART controller and the selected device is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. Utilizing these bits allows two devices to be synchronized. This structure of serial data accompanied by start and stop bits is referred to as a character, as shown in below.†

Figure 21-2: Serial Data Format



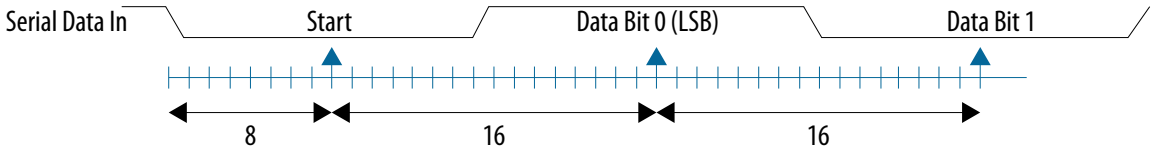
An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to provide the UART controller with the ability to perform simple error checking on the received data.†

The Control Register is used to control the serial character characteristics. The individual bits of the data word are sent after the start bit, starting with the least- significant bit (LSB). These are followed by the optional parity bit, followed by the stop bit(s), which can be 1, 1.5 or 2.†

All the bits in the transmission (with exception to the half stop bit when 1.5 stop bits are used) are transmitted for exactly the same time duration. This is referred to as a Bit Period or Bit Time. One Bit Time equals 16 baud clocks. To ensure stability on the line, the receiver samples the serial input data at approximately the midpoint of the Bit Time once the start bit has been detected. Because the exact number of baud clocks that each bit transmission is known, calculating the midpoint for sampling is not difficult. That is, every 16 baud clocks after the midpoint sample of the start bit.†

Together with serial input debouncing, this feature also contributes to avoid the detection of false start bits. Short glitches are filtered out by debouncing, and no transition is detected on the line. If a glitch is wide enough to avoid filtering by debouncing, a falling edge is detected. However, a start bit is detected only if the line is sampled low again after half a bit time has elapsed. †

Figure 21-3: Receiver Serial Data Sample Points



The baud rate of the UART controller is controlled by the serial clock and the Divisor Latch Register (DLH and DLL).†

Automatic Flow Control

The UART includes 16750-compatible request-to-send (RTS) and clear-to-send (CTS) serial data automatic flow control mode. You enable automatic flow control with the modem control register (`MCR.AFCE`). †

Automatic RTS mode

Automatic RTS mode becomes active when the following conditions occur: †

- RTS (`MCR.RTS` bit and `MCR.AFCE` bit are both set)
- FIFO buffers are enabled (`FCR.FIFOE` bit is set)

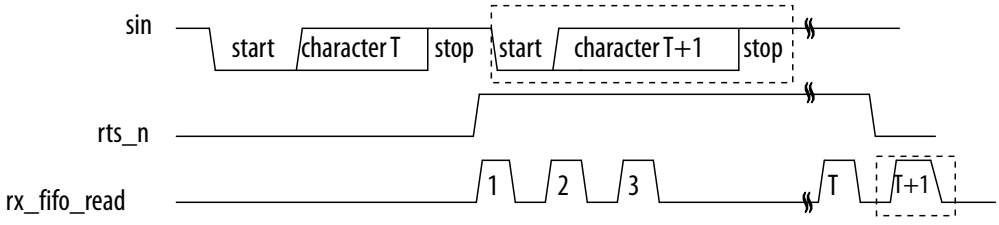
When `rts_n` is connected to the `cts_n` input pin of another UART device, the other UART stops sending serial data until the receive FIFO buffer has available space (until it is completely empty). †

The selectable receive FIFO buffer threshold values are 1, ¼, ½, and 2 less than full. Because one additional character may be transmitted to the UART after `rts_n` is inactive (due to data already having entered the transmitter block in the other UART), setting the threshold to 2 less than full allows maximum use of the FIFO buffer with a margin of one character. †

Once the receive FIFO buffer is completely emptied by reading the receiver buffer register (`RBR_THR_DLL`), `rts_n` again becomes active (low), signaling the other UART to continue sending data.†

Even when you set the correct `MCR` bits, if the FIFO buffers are disabled through `FCR.FIFOE`, automatic flow control is also disabled. When auto RTS is not implemented or disabled, `rts_n` is controlled solely by `MCR.RTS`. In the Automatic RTS Timing diagram, the character T is received because `rts_n` is not detected prior to the next character entering the sending UART transmitter. †

Figure 21-4: Automatic RTS Timing



Automatic CTS mode

Automatic CTS mode becomes active when the following conditions occur: †

- AFCE (MCR.AFCE bit is set)
- FIFO buffers are enabled (through FIFO buffer control register IIR_FCR.FIFOE) bit

When automatic CTS is enabled (active), the UART transmitter is disabled whenever the cts_n input becomes inactive (high). This prevents overflowing the FIFO buffer of the receiving UART. †

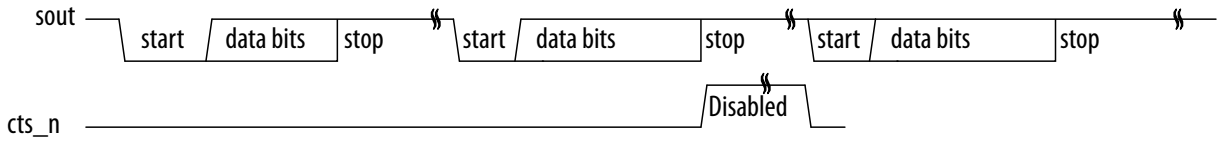
If the cts_n input is not deactivated before the middle of the last stop bit, another character is transmitted before the transmitter is disabled. While the transmitter is disabled, you can continue to write and even overflow to the transmit FIFO buffer. †

Automatic CTS mode requires the following sequence:

1. The UART status register are read to verify that the transmit FIFO buffer is full (UART status register USR.TFNF set to zero). †
2. The current FIFO buffer level is read via the transmit FIFO level (TFL) register. †
3. Programmable THRE interrupt mode must be enabled to access the FIFO buffer full status from the LSR. †

When using the FIFO buffer full status, software can poll this before each write to the transmit FIFO buffer. When the cts_n input becomes active (low) again, transmission resumes. If the FIFO buffers are disabled with the FCR.FIFOE bit, automatic flow control is also disabled regardless of any other settings. When auto CTS is not implemented or disabled, the transmitter is unaffected by cts_n.†

Figure 21-5: Automatic CTS Timing



Clocks

The UART controller is connected to the l4_sp_clk clock. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Resets

The UART controller is connected to the uart_rst_n reset signal. The reset manager drives the signal on a cold or warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Taking the UART Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

The assertion of the UART interrupt output signal occurs when one of the following interrupt types are enabled and active: †

Table 21-4: Interrupt Types and Priority †

Interrupt Type	Priority	Source	Interrupt Reset Control
Receiver line status	Highest	Overrun, parity and framing errors, break condition.	Reading the line status Register.
Received data available	Second	Receiver data available (FIFOs disabled) or RCVR FIFO trigger level reached (FIFOs enabled).	Reading the receiver buffer register (FIFOs disabled) or the FIFO drops below the trigger level (FIFOs enabled)
Character timeout indication	Second	No characters in or out of the Receive FIFO during the last 4 character times and there is at least 1 character in it during this Time.	Reading the receiver buffer Register.
Transmit holding register empty	Third	Transmitter holding register empty (Programmable THRE Mode disabled) or Transmit FIFO at or below threshold (Programmable THRE Mode enabled).	Reading the `IIR` register (if source of interrupt); or, writing into `THR` (FIFOs or Programmable THRE Mode not enabled) or Transmit FIFO above threshold (FIFOs and Programmable THRE Mode enabled).
Modem Status	Fourth	Clear to send or data set ready or ring indicator or data carrier detect. If auto flow control mode is enabled, a change in CTS (that is, DCTS set) does not cause an interrupt.	Reading the Modem status Register.

You can enable the interrupt types with the interrupt enable register (`IER_DLH`).

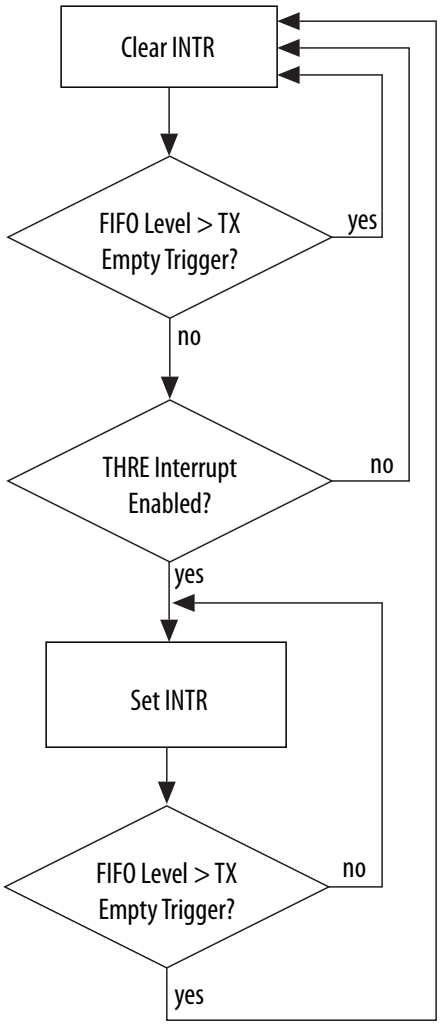
Note: Received Data Available" and "Character Timeout Indication" are enabled by a single bit in the IER_DLH register, because they have the same priority.

Once an interrupt is signaled, you can determine the interrupt source by reading the Interrupt Identity Register (IIR).

Programmable THRE Interrupt

The UART has a programmable THRE interrupt mode to increase system performance. You enable the programmable THRE interrupt mode with the interrupt enable register (`IER_DLH.PTIME`). When the THRE mode is enabled, THRE interrupts and the `dma_tx_req` signal are active at and below a programmed transmit FIFO buffer empty threshold level, as shown in the flowchart. †

Figure 21-6: Programmable THRE Interrupt

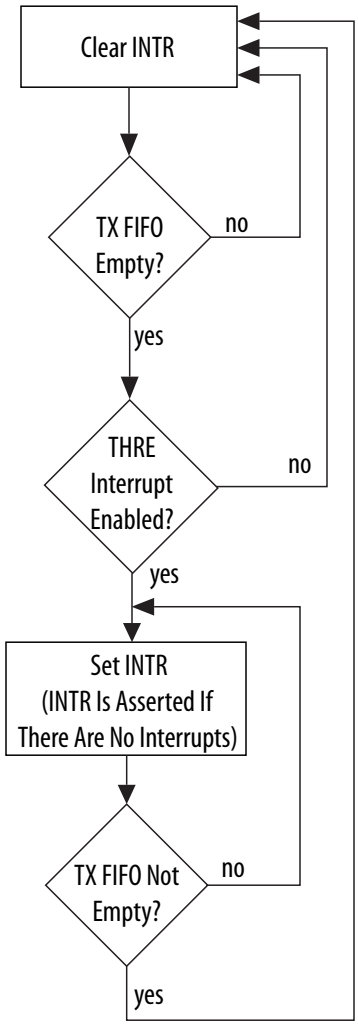


The threshold level is programmed into FCR.TET. The available empty thresholds are empty, 2, ¼, and ½. The optimum threshold value depends on the system's ability to begin a new transmission sequence in a timely manner. However, one of these thresholds should prove optimum in increasing system performance by preventing the transmit FIFO buffer from running empty.

In addition to the interrupt change, line status register (LSR.THRE) also switches from indicating that the transmit FIFO buffer is empty, to indicating that the FIFO buffer is full. This change allows software to fill the FIFO buffer for each transmit sequence by polling LSR.THRE before writing another character. This directs the UART to fill the transmit FIFO buffer whenever an interrupt occurs and there is data to transmit, instead of waiting until the FIFO buffer is completely empty. Waiting until the FIFO buffer is empty reduces performance whenever the system is too busy to respond immediately. You can increase system efficiency when this mode is enabled in combination with automatic flow control.

When not selected or disabled, THRE interrupts and LSR.THRE function normally, reflecting an empty THR or FIFO buffer.

Figure 21-7: Interrupt Generation without Programmable THRE Interrupt Mode



DMA Controller Operation

The UART controller includes a DMA controller interface to indicate when the receive FIFO buffer data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports both single and burst transfers.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the UART controller is 128 entries.

Related Information

DMA Controller on page 16-1
For more information, refer to the DMA Controller chapter.

Transmit FIFO Underflow

During UART serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the decoded level of the Transmit Empty

Trigger (TET) field in the FIFO Control Register (FCR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of data (underflow) causing a STOP to be inserted on the UART bus. To prevent this condition, you must set the watermark level correctly. †

Related Information

DMA Controller on page 16-1
For more information, refer to the DMA Controller chapter.

Transmit Watermark Level

Consider the example where the following assumption is made: †

DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET †

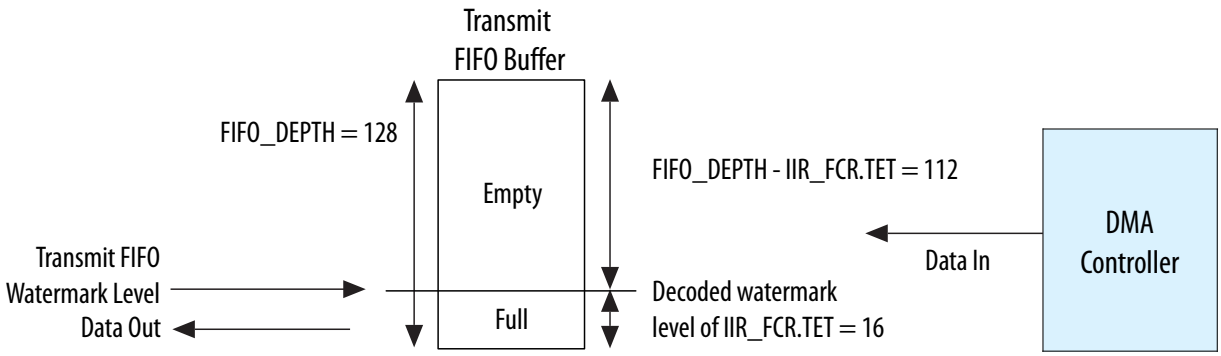
Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

IIR_FCR.TET = 1

IIR_FCR.TET = 1 decodes to a watermark level of 16.

- Transmit FIFO watermark level = decoded watermark level of IIR_FCR.TET = 16 †
- DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET = 112 †
- UART transmit FIFO_DEPTH = 128 †
- Block transaction size =R** 448†

Figure 21-8: Transmit FIFO Watermark Level = 16



The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 448/112 = 4

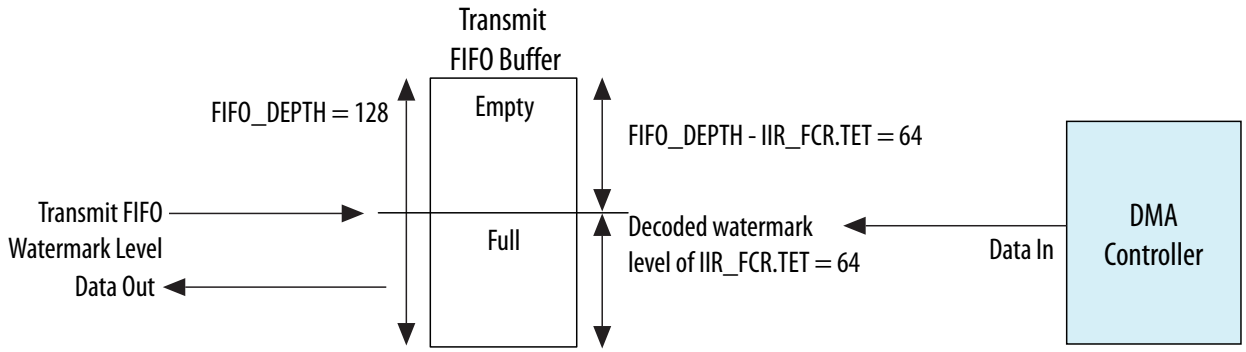
The number of burst transactions in the DMA block transfer is 4. But the watermark level, decoded level of IIR_FCR.TET, is quite low. Therefore, the probability of transmit underflow is high where the UART serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

IIR_FCR.TET = 3

IIR_FCR.TET = 3 decodes to a watermark level of 64.

- Transmit FIFO watermark level = decoded watermark level of IIR_FCR.TET = 64 †
- DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET = 64†
- UART transmit FIFO_DEPTH = 128 †
- Block transaction size = 448 †

Figure 21-9: Transmit FIFO Watermark Level = 64



Number of burst transactions in block: †

Block transaction size/DMA burst length = 448/64 = 7 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, decoded level of IIR_FCR.TET, is high. Therefore, the probability of UART transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the UART transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the UART transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= FIFO_DEPTH - decoded watermark level of IIR_FCR.TET

In case 2: decoded watermark level of IIR_FCR.TET = 64, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length must be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the UART controller has successfully transmitted one data item or more on the UART serial transmit line during the transfer. †

Receive FIFO Overflow

During UART serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the decoded level of Receive Trigger (`RT`) field in the FIFO Control Register (`IIR_FCR`). This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, decoded watermark level of `IIR_FCR.RT`, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a tradeoff between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

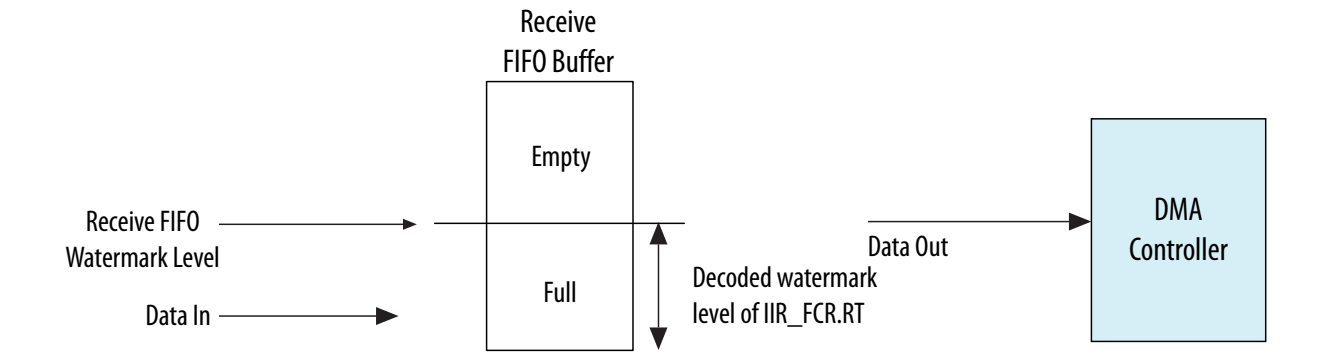
DMA burst length = decoded watermark level of `IIR_FCR.RT` + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, decoded watermark level of `IIR_FCR.RT`. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

The receive FIFO will not be empty at the end of the source burst transaction if the UART controller has successfully received one data item or more on the UART serial receive line during the burst. †

Figure 21-10: Receive FIFO Buffer



UART Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

rbr_thr_dll

This is a multi-function register. This register holds receives and transmit data and controls the least-signficant 8 bits of the baud rate divisor.

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC02000
uart1	0xFFC03000	0xFFC03000

rbr_thr_dll Fields

Bit	Name	Description	Access	Reset
7:0	value	Receive Buffer Register: This register contains the data byte received on the serial input port (uart_rxd). The data in this register is valid only if the Data Ready (bit [0] in the Line Status Register(LSR)) is set to 1. If FIFOs are disabled(bit[0] of Register FCR is set to 0) the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled(bit [0] of Register FCR is set to 1) this register accesses the head of the receive FIFO. If the receive FIFO is full, and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur. Transmit Holding Register: This register contains data to be transmitted on the serial output port. Data should only be written to the THR when the THR Empty bit [5] of the LSR Register is set to 1. If FIFOs are disabled (bit [0] of Register FCR) is set to 0 and THRE is set to 1, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of Register FCR is set to 1 and THRE is set up to 128 characters of data may be written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost. Divisor Latch Low: This register makes up the lower 8-bits of a 16-bit, Read/ write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 1. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor) Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.	RW	0x0

ier_dlh

This is a multi-function register. This register enables/disables receive and transmit interrupts and also controls the most-significant 8-bits of the baud rate divisor. Divisor Latch High Register: This register is accessed when the DLAB bit [7] of the LCR Register is set to 1.Bits[7:0] contain the high order 8-bits of the baud rate divisor.The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor): Note that with the Divisor Latch Registers (DLLand DLH) set to zero, the baud clock is disabled and no

serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data. Interrupt Enable Register: This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 0.Allows control of the Interrupt Enables for transmit and receive functions.

Bit	Name	Description	Access	Reset
7:6	rt	This register is configured to implement FIFOs. Bits[7:6], Rx Trigger (or RT): This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt will be generated. In auto flow control mode it is used to determine when the uart_rts_n signal will be de-asserted. It also determines when the uart_dma_rx_req_n signal will be asserted when in certain modes of operation. **Value** — **Description** 0x0 — one character in fifo 0x1 — FIFO 1/4 full 0x2 — FIFO 1/2 full 0x3 — FIFO 2 less than full	WO	0x0
5:4	tet	This is used to select the empty threshold level at which the THRE Interrupts will be generated when the mode is active. It also determines when the uart DMA transmit request signal uart_dma_tx_req_n will be asserted when in certain modes of operation. **Value** — **Description** 0x0 — FIFO empty 0x1 — Two characters in FIFO 0x2 — FIFO 1/4 full 0x3 — FIFO 1/2 full	WO	0x0

Bit	Name	Description	Access	Reset
3	dmam	This determines the DMA signalling mode used for the uart_dma_tx_req_n and uart_dma_rx_req_n output signals when additional DMA handshaking signals are not selected. DMA mode 0 supports single DMA data transfers at a time. In mode 0, the uart_dma_tx_req_n signal goes active low under the following conditions: -When the Transmitter Holding Register is empty in non-FIFO mode. -When the transmitter FIFO is empty in FIFO mode with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is at or below the programmed threshold with Programmable THRE interrupt mode enabled. It goes inactive under the following conditions -When a single character has been written into the Transmitter Holding Register or transmitter FIFO with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is above the threshold with Programmable THRE interrupt mode enabled. DMA mode 1 supports multi-DMA data transfers, where multiple transfers are made continuously until the receiver FIFO has been emptied or the transmit FIFO has been filled. In mode 1 the uart_dma_tx_req_n signal is asserted under the following conditions: -When the transmitter FIFO is empty with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is at or below the programmed threshold with Programmable THRE interrupt mode enabled. **Value** — **Description** 0x0 — Single DMA Transfer Mode 0x1 — Multiple DMA Transfer Mode	WO	0x0
2	xfifor	Resets the control portion of the transmit FIFO and treats the FIFO as empty. This will also de-assert the DMA Tx request and single signals when additional DMA handshaking is used. Note that this bit is 'self-clearing' and it is not necessary to clear this bit. **Value** — **Description** 0x0 — No Reset of Tx FIFO Control 0x1 — Resets Tx FIFO Control	WO	0x0

Bit	Name	Description	Access	Reset
1	rfifor	Resets the control portion of the receive FIFO and treats the FIFO as empty. This will also de-assert the DMA Rxrequest and single signals. Note that this bit is self-clearing' and it is not necessary to clear this bit. **Value** **Description** 0x0 No Reset of Rx FIFO Control 0x1 Resets of Rx FIFO Control	WO	0x0
0	fifoe	Enables/disables the transmit (Tx) and receive (Rx) FIFO's. Whenever the value of this bit is changed both the Tx and Rx controller portion of FIFO's will be reset. **Value** **Description** 0x0 FIFOs disabled 0x1 FIFOs enabled	WO	0x0

lcr

Formats serial data.

Module Instance	Base Address	Register Address

lcr Fields

Bit	Name	Description	Access	Reset
7	dlab	Used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.	RW	0x0

Bit	Name	Description	Access	Reset
6	break	This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.	RW	0x0
4	eps	This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked. **Value** **Description** 0x0 odd parity 0x1 even parity	RW	0x0
3	pen	This bit is used to enable and disable parity generation and detection in a transmitted and received data character. **Value** **Description** 0x0 parity disabled 0x1 parity enabled	RW	0x0
2	stop	Number of stop bits. Used to select the number of stop bits per character that the peripheral will transmit and receive.Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. **Value** **Description** 0x0 one stop bit 0x1 1.5 stop bits when DLS (LCR[1:0]) is zero	RW	0x0

Bit	Name	Description	Access	Reset
1:0	dls	Data Length Select.Selects the number of data bits per character that the peripheral will transmit and receive. **Value** — **Description** 0x0 — 5 bits 0x1 — 6 bits 0x2 — 7 bits 0x3 — 8 bits	RW	0x0

mcr

Reports various operations of the modem signals

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC02010
uart1	0xFFC03000	0xFFC03010

Offset: 0x10

Access: RW

Bit Fields

mcr Fields

Bit	Name	Description	Access	Reset
5	afce	When FIFOs are enabled, the Auto Flow Control enable bits are active. **Value** — **Description** 0x0 — Auto Flow Control Mode disabled 0x1 — Auto Flow Control Mode enabled	RW	0x0

Bit	Name	Description	Access	Reset
4	loopback	This is used to put the UART into a diagnostic mode for test purposes. If UART mode is NOT active, bit [6] of the modem control register MCR is set to zero, data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (uart_dsr_n, uart_cts_n, uart_ri_n, uart_dcd_n) are disconnected and the modem control outputs (uart_dtr_n, uart_rts_n, uart_out1_n, uart_out2_n) are loopedback to the inputs, internally.	RW	0x0
3	out2	This is used to directly control the user-designated uart_out2_n output. The value written to this location is inverted and driven out on uart_out2_n Note: In Loopback mode bit 4 of the modem control register (MCR) is set to one, the uart_out2_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0x0 uart_out2_n de-asserted (logic 1) 0x1 uart_out2_n asserted (logic 0)	RW	0x0
2	out1	The value written to this location is inverted and driven out on uart_out1_n pin. Note that in Loopback mode (MCR[4] set to one), the uart_out1_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0x0 uart_out1_n de-asserted (logic 1) 0x1 uart_out1_n asserted (logic 0)	RW	0x0

Bit	Name	Description	Access	Reset
1	rts	This is used to directly control the Request to Send (uart_rts_n) output. The Request to Send (uart_rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the uart_rts_n signal is set low by programming MCR[1] (RTS) to a high. If Auto Flow Control is active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the uart_rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (uart_rts_n is inactive high when above the threshold). The uart_rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the uart_rts_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0x0 uart_rts_n de-asserted (logic 1) 0x1 uart_rts_n asserted (logic 0)	RW	0x0
0	dtr	This is used to directly control the Data Terminal Ready output. The value written to this location is inverted and driven out on uart_dtr_n, that is: The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that Loopback mode bit [4] of MCR is set to one, the uart_dtr_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0x0 uart_dtr_n de-asserted (logic 1) 0x1 uart_dtr_n asserted (logic 0)	RW	0x0

lsr

Reports status of transmit and receive.

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC02014

lsr Fields

Bit	Name	Description	Access	Reset
7	rfe	This bit is only relevant when FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. **Value** **Description** 0x0 no error in Rx FIFO 0x1 error in Rx FIFO	RO	0x0
6	temt	If in FIFO mode and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. **Value** **Description** 0x0 Transmit Empty not set 0x1 Transmit Empty set	RO	0x1
5	thre	If THRE mode is disabled (IER[7] set to zero) this bit indicates that the THR or Tx FIFO is empty. This bit is set whenever data is transferred from the THR or Tx FIFO to the transmitter shift register and no new data has been written to the THR or Tx FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If both THRE and FIFOs are enabled, both (IER[7] set to one and FCR[0] set to one respectively), the functionality will indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] thresholdsetting.	RO	0x1

Bit	Name	Description	Access	Reset
4	bi	This is used to indicate the detection of a break sequence on the serial input data. Set whenever the serial input, sin, is held in a logic 0 state for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. The character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit.	RO	0x0
3	fe	This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit(LSR[3]) will be set if a break interrupt has occurred, as indicated by a Break Interrupt BIT bit (LSR[4]). Reading the LSR clears the FE bit. **Value** — **Description** 0x0 — no framing error 0x1 — framing error	RO	0x0
2	pe	This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. Since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). Reading the LSR clears the PE bit. **Value** — **Description** 0x0 — no parity error 0x1 — no parity error	RO	0x0

Bit	Name	Description	Access	Reset
1	oe	This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost.Reading the LSR clears the OE bit. **Value** **Description** 0x0 no overrun error 0x1 overrun error	RO	0x0
0	dr	This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode. **Value** **Description** 0x0 no data ready 0x1 data ready	RO	0x0

msr

It should be noted that whenever bits 0, 1, 2 or 3 are set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

Bit	Name	Description	Access	Reset
7	dcd	This is used to indicate the current state of the modem control line uart_dcd_n. That is this bit is the complement uart_dcd_n. When the Data Carrier Detect input (uart_dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (uart_out2). **Value** **Description** 0x0 uart_dcd_n input is de-asserted (logic 1) 0x1 uart_dcd_n input is asserted (logic 0)	RO	0x0
6	ri	This bit is used to indicate the current state of the modem control line uart_ri_n. That is this bit is the complement uart_ri_n. When the Ring Indicator input (uart_ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode bit [4] of register MCR set to one, RI is the same as bit [2] uart_out1_n of register MCR. **Value** **Description** 0x0 uart_ri_n input is de-asserted (logic 1) 0x1 uart_ri_n input is asserted (logic 0)	RO	0x0

Bit	Name	Description	Access	Reset
5	dsr	This is used to indicate the current state of the modem control line uart_dsr_n. That is this bit is the complement f uart_dsr_n. When the Data Set Ready input (uart_dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the uart. In Loopback Mode bit [4] of register MCR is set to one, DSR is the same as bit [0] (DTR) of register MCR. **Value** **Description** 0x0 uart_dsr_n input is de-asserted (logic 1) 0x1 uart_dsr_n input is asserted (logic 0)	RO	0x0
4	cts	This is used to indicate the current state of the modem control line uart_cts_n. That is, this bit is the complement uart_cts_n. When the Clear to Send input (uart_cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the uart. In Loopback Mode bit [4] of register MCR is set to one, CTS is the same as bit [1] RTS of register MCR. **Value** **Description** 0x0 uart_cts_n input is de-asserted (logic 1) 0x1 uart_cts_n input is asserted (logic 0)	RO	0x0
3	ddcd	This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode bit [4] of register MCR is set to one, DDCD reflects changes bit [3] uart_out2 of register MCR. Note: If the DDCD bit is not set and the uart_dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the uart_dcd_n signal remains asserted. **Value** **Description** 0x0 no change on uart_dcd_n since last read of MSR 0x1 change on uart_dcd_n since last read of MSR	RO	0x0

Bit	Name	Description	Access	Reset
2	teri	This is used to indicate that a change on the input uart_ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode bit [4] of register MCR is set to one, TERI reflects when bit [2] of register MCR has changed state from a high to a low. **Value** **Description** 0x0 no change on uart_ri_n since last read of MSR 0x1 change on uart_ri_n since last read of MSR	RO	0x0
1	ddsr	This is used to indicate that the modem control line uart_dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit.In Loopback Mode (MCR[4] set to one), DDSR reflects changes on bit [0] DTR of register MCR . Note, if the DDSR bit is not set and the uart_dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the uart_dsr_n signal remains asserted. **Value** **Description** 0x0 no change on uart_dsr_n since last read of MSR 0x1 change on uart_dsr_n since last read of MSR	RO	0x0
0	dcts	This is used to indicate that the modem control line uart_cts_n has changed since the last time the MSR was read. That is: Reading the MSR clears the DCTS bit. In Loopback Mode bit [4] of MCR set to one, DCTS reflects changes on bit [1] RTS of register MCR. Note: If the DCTS bit is not set and the uart_cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the uart_cts_n signal remains asserted. **Value** **Description** 0x0 no change on uart_cts_n since last read of MSR 0x1 change on uart_cts_n since last read of MSR	RO	0x0

Reserved								srbr RW 0x0							

srbr Fields

Bit	Name	Description	Access	Reset
7:0	srbr	This is a shadow register for the RBR and has been allocated one 32-bit location so as to accommodate burst accesses from the master.This register contains the data byte received on the serial input port (sin). The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If FIFOs are disabled, bit [0] of register FCR set to zero, the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur.	RW	0x0

sthr

Used to accomadate burst accesses from the master.

Module Instance	Base Address	Register Address

Reserved								sthr RW 0x0							

sthr Fields

Bit	Name	Description	Access	Reset
7:0	sthr	This is a shadow register for the THR and has been allocated sixteen 32-bit locations so as to accommodate burst accesses from the master. This register contains data to be transmitted on the serial output port (sout). Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If FIFO's are disabled bit [0] of register FCR set to zero and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of register FCR set to one and THRE is set, 128 characters of data may be written to the THR before the FIFO is full. The UART FIFO depth is configured for 128 characters. Any attempt to write data when the FIFO is full results in the write data being lost.	RW	0x0

far

This register is used in FIFO access testing.

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC02070

srts Fields

Bit	Name	Description	Access	Reset
0	srts	This is used to directly control the Request to Send (uart_rts_n) output. The Request to Send (uart_rts_n) output is used to inform the modem or data set that the UART is read to exchange data. The uart_rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, (MCR[5] set to one) and FIFO's are enabled (FCR[0] set to one), the uart_rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (uart_rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] set to one), the uart_rts_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0x1 uart_rts_n logic0 0x0 uart_rts_n logic1	RW	0x0

sbcr

This is a shadow register for the Break bit [6] of the register LCR. This can be used to remove the burden of having to performing a read modify write on the LCR.

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC02090

11	shadow	Configures the peripheral to have seven additional registers that shadow some of the existing register bits that are regularly modified by software. These can be used to reduce the software overhead that is introduced by having to perform read-modify writes. **Value** **Description** 0x1 Shadow Supported	RO	0x1
10	fifo_stat	Configures the peripheral to have three additional FIFO status registers. **Value** **Description** 0x1 FIFO Stat Supported	RO	0x1
9	fifo_access	Configures the peripheral to have a programmable FIFO access mode. This is used for test purposes, to allow the receiver FIFO to be written and the transmit FIFO to be read when FIFOs are implemented and enabled. **Value** **Description** 0x1 FIFO Access Supported	RO	0x1
8	additional_feat	Configures the uart to include fifo status register, shadow registers and encoded parameter register. **Value** **Description** 0x1 Additional Features Supported	RO	0x1

Bit	Name	Description	Access	Reset
7	sir_lp_mode	LP Sir Mode not used in this application. **Value** **Description** 0x0 LP Sir Mode Not Supported	RO	0x0
6	sir_mode	Sir mode not used in this application. **Value** **Description** 0x0 Sir Mode Not Supported	RO	0x0
5	thre_mode	Programmable Transmitter Hold Register Empty interrupt **Value** **Description** 0x1 Programmable Tx Hold Reg. Empty interrupt present	RO	0x1
4	afce_mode	Allows auto flow control. **Value** **Description** 0x1 Auto Flow	RO	0x1
1:0	apbdatawidth	Fixed to support an ABP data bus width of 32-bits. **Value** **Description** 0x2 APB Data Width = 32-bits	RO	0x2

Document Revision History

Table 21-5: Document Revision History

Date	Version	Changes
November 2015	2015.11.02	Renamed *Interface Pins* section to *HPS I/O Pins* and moved this section and *FPGA Routing* under *UART Controller Signal Description*
May 2015	2015.05.04	Maintenance release.
December 2014	2014.12.15	• Maintenance release. • Added *Taking the UART Out of Reset* section.
June 2014	2014.06.30	• UART(RS232) Serial Protocol topic added • Interrupts section updated • Updated Interrupt type table • Added address map and register descriptions
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Minor formatting updates.
November 2012	1.2	Minor updates.
May 2012	1.1	Added programming model, address map and register definitions, and reset sections.
January 2012	1.0	Initial release.

General-Purpose I/O Interface 22

2015.11.02

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides three general-purpose I/O (GPIO) interface modules. The GPIO modules are instances of the Synopsys® DesignWare® APB General Purpose Programming I/O (DW_apb_gpio) peripheral.† (61)

Features of the GPIO Interface

The GPIO interface offers the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 71 I/O pins and 14 input-only pins

GPIO Interface Block Diagram and System Integration

The figure below shows a block diagram of the GPIO interface. The following table shows a pin table of the GPIO interface:

Figure 22-1: Arria V SoC GPIO

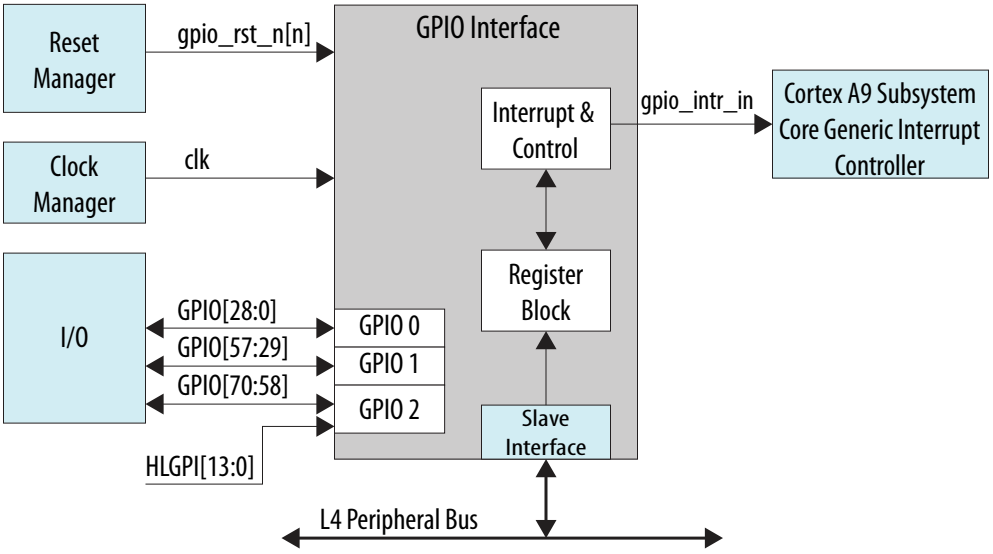

Table 22-1: GPIO Interface pin table

Pin Name	Mapped to GPIO signal name	Comments
GPIO [28:0]	GPIO 0 [28:0]	Input / Output
GPIO [57:29]	GPIO 1 [28:0]	Input / Output
GPIO [70:58]	GPIO 2 [12:0]	Input / Output
HLGPI [13:0]	GPIO 2 [26:13]	Input only

Functional Description of the GPIO Interface

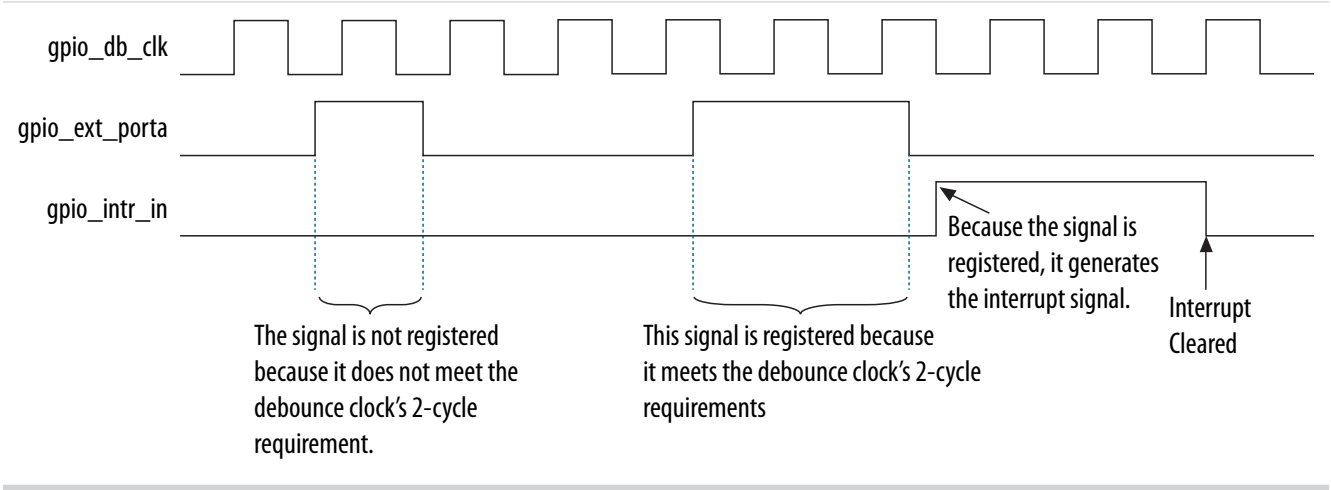
Debounce Operation

The GPIO modules provided in the HPS include optional debounce capabilities. The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock, `gpio_db_clk`. †

When input signals are debounced using the `gpio_db_clk` debounce clock, the signals must be active for a minimum of two cycles of the debounce clock to guarantee that they are registered. Any input pulse widths less than a debounce clock period are filtered out. If the input signal pulse width is between one and two debounce clock widths, it may or may not be filtered out, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered. †

The figure below shows a timing diagram of the debounce circuitry for both cases: a bounced input signal, and later, a propagated input signal.

Figure 22-2: Debounce Timing With Asychronous Reset Flip-Flops



Note: Enabling the debounce circuitry increases interrupt latency by two clock cycles of the debounce clock.

Pin Directions

The pins GPIO0 through GPIO70 can be configured to be either input or output signals. The pins HLGPI0 through HLGPI13 share pins with the HPS DDR controller and are input-only signals.

Taking the GPIO Interface Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

GPIO Interface Programming Model

Debounce capability for each of the input signals can be enabled or disabled under software control by setting the corresponding bits in the gpio_debounce register, accordingly. The debounce clock must be stable and operational before the debounce capability is enabled.

Under software control, the direction of the external I/O pad is controlled by a write to the gpio_swportx_ddr register. When configured as input mode, reading gpio_ext_porta would read the values on the signal of the external I/O pad. When configured as output mode, the data written to the gpio_swporta_dr register drives the output buffer of the I/O pad. The same pins are shared for both input and output modes, so they cannot be configured as input and output modes at the same time. †

GPIO Interface Address Map and Register Definitions

The address map and register definitions for the GPIO consist of the following regions:

- GPIO Module 0
- GPIO Module 1
- GPIO Module 2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpio_inten RW 0x0															

gpio_inten Fields

Bit	Name	Description	Access	Reset
28:0	gpio_inten	Allows each bit of Port A Data Register to be configured for interrupt capability. Interrupts are disabled on the corresponding bits of Port A Data Register if the corresponding data direction register is set to Output. Note that only bits[26:0] are implemented for gpio2. **Value** — **Description** 0x0 — Disable Interrupt on Port A 0x1 — Enable Interrupt on Port A	RW	0x0

gpio_intmask

Controls which pins cause interrupts on Port A Data Register inputs.

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF708034
gpio1	0xFF709000	0xFF709034
gpio2	0xFF70A000	0xFF70A034

Offset: 0x34

Access: RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpio_intmask RW 0x0															

gpio_intmask Fields

Bit	Name	Description	Access	Reset
28:0	gpio_intmask	Controls whether an interrupt on Port A Data Register can generate an interrupt to the interrupt controller by not masking it. The unmasked status can be read as well as the resultant status after masking. Note that only bits[26:0] are implemented for gpio2. **Value** **Description** 0x0 Interrupt bits are unmasked 0x1 Mask Interrupt	RW	0x0

gpio_inttype_level

The interrupt level register defines the type of interrupt (edge or level).

Module Instance	Base Address	Register Address
gpio0	0xFF708000	0xFF708038
gpio1	0xFF709000	0xFF709038
gpio2	0xFF70A000	0xFF70A038

Offset: 0x38

Access: RW

Bit Fields

Timer 23

2015.11.02

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus.The timers optionally generate an interrupt when the 32-bit binary count-down timer reaches zero. The timers are instances of the Synopsys® DesignWare® APB Timers (DW_apb_timers) peripheral.(62)

Related Information

Cortex-A9 MPCore on page 9-4
The MPU subsystem provides additional timers. For more information about the timers in the MPU, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

Features of the Timer

- Supports interrupt generation
- Supports free-running mode
- Supports user-defined count mode

Timer Block Diagram and System Integration

Each timer includes a slave interface for control and status register (CSR) access, a register block, and a programmable 32-bit down counter that generates interrupts on reaching zero. The timer operates on a single clock domain driven by the clock manager.

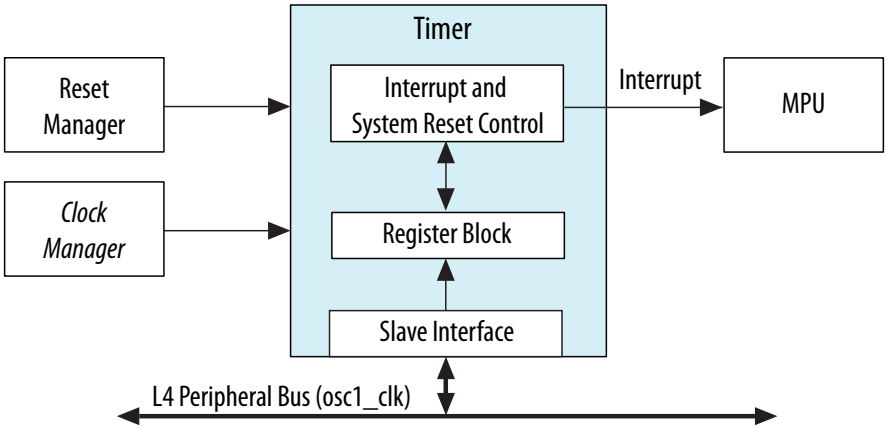
Figure 23-1: Timer Block Diagram



Functional Description of the Timer

The 32-bit timer counts down from a programmed value and generates an interrupt when the count reaches zero. The timer has an independent clock input connected to the system clock signal or to an external clock source. †

The timer supports the following modes of operation:

- Free-running mode—decrementing from the maximum value (0xFFFFFFFF). Reloads maximum value upon reaching zero.
- User-defined count mode—generates a periodic interrupt. Decrements from the user-defined count value loaded from the timer1 load count register (`timer1loadcount`). Reloads the user-defined count upon reaching zero.

The initial value for the timer (that is, the value from which it counts down) is loaded into the timer by the `timer1loadcount` register. The following events can cause a timer to load the initial count from the `timer1loadcount` register: †

- Timer is enabled after being reset or disabled
- Timer counts down to 0

Clocks

Table 23-1: Timer Clock Characteristics

Timer	System Clock	Notes
OSC1 timer 0	`osc1_clk`	—
OSC1 timer 1		

Timer	System Clock	Notes
SP timer 0	l4_sp_clk	Timer must be disabled if clock frequency changes
SP timer 1		

The timers above are labeled according to the clock it receives. OSC timers receive the oscillator clock `osc1_clk` and the SP timers receives the l4 slave peripheral clock `l4_sp_clk` .

SP timer 0 and SP timer 1 must be disabled before `l4_sp_clk` is changed to another frequency. You can then re-enable the timer once the clock frequency change takes effect. You cannot change the frequency of OSC1 timer 0 and OSC1 timer 1.

Related Information

Clock Manager on page 2-1
For more information about clock performance, refer to the *Clock Manager* chapter.

Resets

The timers are reset by a cold or warm reset. Resetting the timers produces the following results in the following order:

1. The timer is disabled.
2. The interrupt is enabled.
3. The timer enters free-running mode.
4. The timer count load register value is set to zero.

Interrupts

The timer1 interrupt status (`timer1intstat`) and timer1 end of interrupt (`timer1eoi`) registers handle the interrupts. The `timer1intstat` register allows you to read the status of the interrupt. Reading from the `timer1eoi` register clears the interrupt. †

The timer1 control register (`timer1controlreg`) contains the timer1 interrupt mask bit (`timer1_interrupt_mask`) to mask the interrupt. In both the free-running and user-defined count modes of operation, the timer generates an interrupt signal when the timer count reaches zero and the interrupt mask bit of the control register is high.

If the timer interrupt is set, then it is cleared when the timer is disabled.

FPGA Interface

The timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Qsys.

Related Information

Interrupts on page 26-5
For more information about configuring and routing timer interrupts, refer to the interrupt section of the*Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual.*

Timer Programming Model

Initialization

To initialize the timer, perform the following steps: †

1. Initialize the timer through the `timer1controlreg` register: †
   - Disable the timer by writing a 0 to the timer1 enable bit (`timer1_enable`) of the `timer1controlreg` register. †

   Note: Before writing to a timer1 load count register (`timer1loadcount`), you must disable the timer by writing a 0 to the `timer1_enable` bit of the `timer1controlreg` register to avoid potential synchronization problems. †
   - Program the timer mode—user-defined count or free-running—by writing a 0 or 1, respectively, to the timer1 mode bit (`timer1_mode`) of the `timer1controlreg` register. †
   - Set the interrupt mask as either masked or not masked by writing a 1 or 0, respectively, to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †
2. Load the timer counter value into the `timer1loadcount` register. †
3. Enable the timer by writing a 1 to the `timer1_enable` bit of the `timer1controlreg` register. †

Enabling the Timer

When a timer transitions to the enabled state, the current value of `timer1loadcount` register is loaded into the timer counter. †

1. To enable the timer, write a 1 to the `timer1_enable` bit of the `timer1controlreg` register.

Disabling the Timer

When the timer enable bit is cleared to 0, the timer counter and any associated registers in the timer clock domain, are asynchronously reset. †

1. To disable the timer, write a 0 to the `timer1_enable` bit. †

Loading the Timer Countdown Value

When a timer counter is enabled after being reset or disabled, the count value is loaded from the `timer1loadcount` register; this occurs in both free-running and user-defined count modes. †

When a timer counts down to 0, it loads one of two values, depending on the timer operating mode: †

- User-defined count mode—timer loads the current value of the `timer1loadcount` register. Use this mode if you want a fixed, timed interrupt. Designate this mode by writing a 1 to the `timer1_mode` bit of the `timer1controlreg` register. †
- Free-running mode—timer loads the maximum value (0xFFFFFFFF). The timer max count value allows for a maximum amount of time to reprogram or disable the timer before another interrupt occurs. Use this mode if you want a single timed interrupt. Enable this mode by writing a 0 to the `timer1_mode` bit of the `timer1controlreg` register. †

Servicing Interrupts

Clearing the Interrupt

An active timer interrupt can be cleared in two ways.

1. If you clear the interrupt at the same time as the timer reaches 0, the interrupt remains asserted. This action happens because setting the timer interrupt takes precedence over clearing the interrupt. †
2. To clear an active timer interrupt, read the `timer1eoi` register or disable the timer. When the timer is enabled, its interrupt remains asserted until it is cleared by reading the `timer1eoi` register. †

Checking the Interrupt Status

You can query the interrupt status of the timer without clearing its interrupt.

1. To check the interrupt status, read the `timer1intstat` register. †

Masking the Interrupt

The timer interrupt can be masked using the `timer1controlreg` register.

To mask an interrupt, write a 1 to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- OSC1 Timer Module 0
- OSC1 Timer Module 1
- SP Timer Module 0
- SP Timer Module 1

Watchdog Timer 24

2015.11.02

av_5v4 Subscribe Send Feedback

The watchdog timers are peripherals you can use to recover from system lockup that might be caused by software or system related issues. The hard processor system (HPS) provides two programmable watchdog timers, which are connected to the level 4 (L4) peripheral bus. The watchdog timers are instances of the Synopsys® DesignWare® APB Watchdog Timer (DW_apb_wdt) peripheral. (63)

The microprocessor unit (MPU) subsystem provides two additional watchdog timers.

Related Information

Cortex-A9 MPCore on page 9-4

For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

Features of the Watchdog Timer

The following list describes the features of the watchdog timer:

- Programmable 32-bit timeout range
- Timer counts down from a preset value to zero, then performs one of the following user-configurable operations:
  - Generates a system reset †
  - Generates an interrupt, restarts the timer, and if the timer is not cleared before a second timeout occurs, generates a system reset

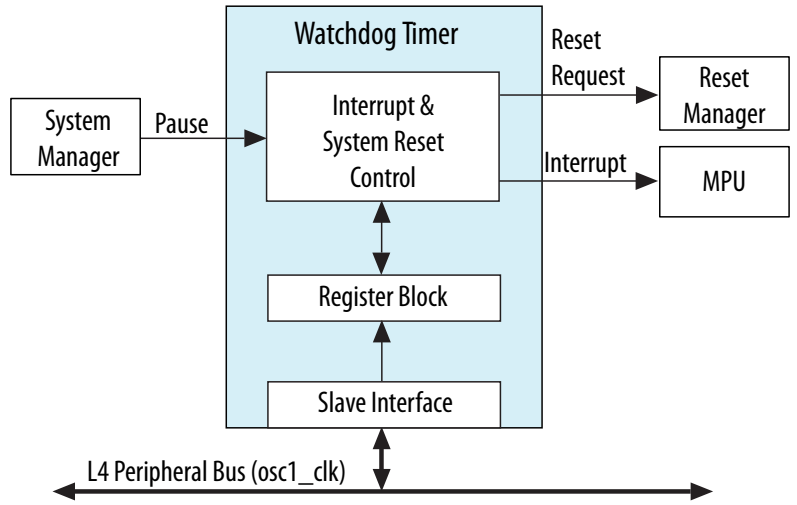
Watchdog Timer Block Diagram and System Integration

Each watchdog timer consists of a slave interface for control and status register (CSR) access, a register block, and a 32-bit down counter that operates on the slave interface clock (`osc1_clk`). A pause input, driven by the system manager, optionally pauses the counter when a CPU is being debugged.

The watchdog timer drives an interrupt request to the MPU and a reset request to the reset manager.

Figure 24-1: Watchdog Timer Block Diagram



Related Information

  For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

Functional Description of the Watchdog Timer

Watchdog Timer Counter

Each watchdog timer is a programmable, little-endian down counter that decrements by one on each clock cycle. The watchdog timer supports 16 fixed timeout period values, Software chooses which timeout periods are desired. A timeout period is 2<*n*> `osc1_clk` clock periods, where *n* is an integer from 16 to 31 inclusive.

Software must regularly restart the timer (which reloads the counter with the restart timeout period value) to indicate that the system is functioning normally. Software can reload the counter at any time by writing to the restart register. If the counter reaches zero, the watchdog timer has timed out, indicating an unrecoverable error has occurred and a system reset is needed.

Software configures the watchdog timer to one of the following output response modes:

- On timeout, generate a reset request.
- On timeout, assert an interrupt request and restart the watchdog timer. Software must service the interrupt and reset the watchdog timer before a second timeout occurs. Otherwise, generate a reset request.

If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

Note: After the watchdog timer reaches zero and generates a reset or interrupt, the counter resets and continues to count.

Related Information

- **Setting the Timeout Period Values** on page 24-4
- **Selecting the Output Response Mode** on page 24-4
- **Reloading a Watchdog Counter** on page 24-5

Watchdog Timer Pause Mode

The watchdog timers can be paused during debugging. The watchdog timer pause mode is controlled by the system manager. The following options are available:

- Pause the timer while either CPU0 or CPU1 is in debug mode
- Pause the timer while only CPU1 is in debug mode
- Pause the timer while only CPU0 is in debug mode
- Do not pause the timer

When pause mode is enabled, the system manager pauses the watchdog timer while debugging. When pause mode is disabled, the watchdog timer runs while debugging.

At reset, the watchdog pausing feature is enabled for both CPUs by default.

Related Information

Pausing a Watchdog Timer on page 24-5

Watchdog Timer Clocks

Each watchdog timer is connected to the `osc1_clk` clock so that timer operation is not dependent on the phase-locked loops (PLLs) in the clock manager. This independence allows recovery from software that inadvertently programs the PLLs in the clock manager incorrectly.

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Watchdog Timer Resets

Watchdog timers are reset by a cold or warm reset from the reset manager, and are disabled when exiting reset. †

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Taking the Watchdog Timer Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

FPGA Interface

The watchdog timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Qsys

Watchdog Timer Programming Model

Setting the Timeout Period Values

The watchdog timers have a dual timeout period. The counter uses the initial start timeout period value the first the timer is started. All subsequent restarts use the restart timeout period. The valid values are $2^{(16+<i>)} - 1$ clock cycles, where i is an integer from 0 to 15. To set the programmable timeout periods, perform the following actions in no specific order:

Note: Set the timeout values before enabling the timer.

- To set the initial start timeout period, write i to the timeout period for the initialization field (`top_init`) of the watchdog timeout range register (`wdt_torr`).
- To set the restart timeout period, write i to the timeout period field (`top`) of the `wdt_torr` register

Selecting the Output Response Mode

The watchdog timers have two output response modes. To select the desired mode, perform one of the following actions:

- To generate a system reset request when a timeout occurs, write 0 to the output response mode bit (`rmod`) of the watchdog timer control register (`wdt_cr`).
- To generate an interrupt and restart the timer when a timeout occurs, write 1 to the `rmod` field of the `wdt_cr` register.

If a restart occurs at the same time the watchdog counter reaches zero, a system reset is not generated. †

Related Information

Watchdog Timer Counter on page 24-2

Enabling and Initially Starting a Watchdog Timer

To enable and start a watchdog timer, write the value 1 to the watchdog timer enable bit (`wdt_en`) of the `wdt_cr` register.

Reloading a Watchdog Counter

To reload a watchdog counter, write the value 0x76 to the counter restart register (`wdt_crr`). This unique 8-bit value is used as a safety feature to prevent accidental restarts.

Pausing a Watchdog Timer

Pausing the watchdog timers is controlled by the L4 watchdog debug register (`wddbg`) in the system manager.

Related Information

Features of the System Manager on page 5-1
For more information, refer to the *System Manager* chapter.

Disabling and Stopping a Watchdog Timer

The watchdog timers are disabled and stopped by resetting them from the reset manager.

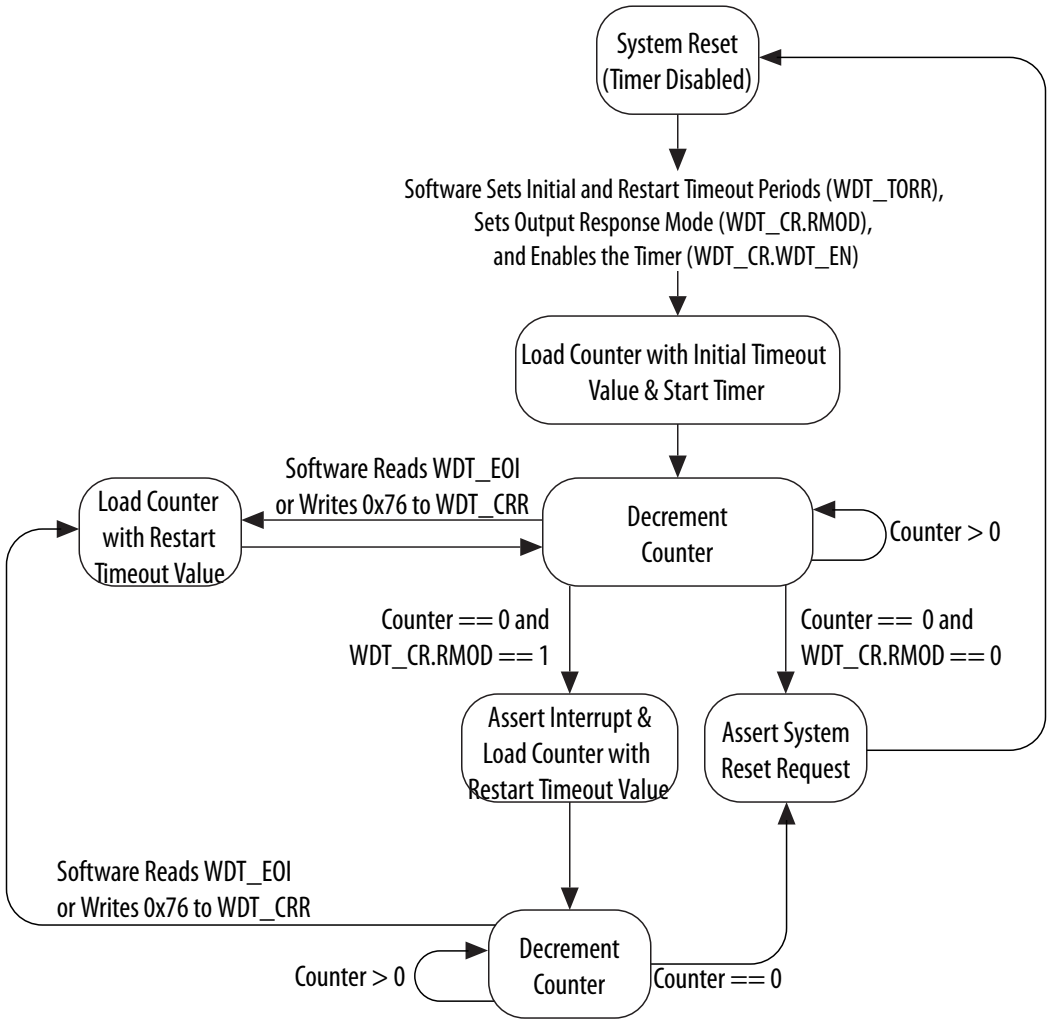
Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Watchdog Timer State Machine

The following figure illustrates the behavior of the watchdog timer, including the behavior of both output response modes. Once initialized, the counter decrements at every clock cycle. The state machine remains in the Decrement Counter state until the counter reaches zero, or the watchdog timer is restarted. If software reads the interrupt clear register (`wdt_eoi`), or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to Decrement Counter.

Figure 24-2: Watchdog Timer State Machine



If the counter reaches zero, the state changes based on the value of the output response mode setting defined in the `rmod` bit of the `wdt_cr` register. If the `rmod` bit of the `wdt_cr` register is 0, the output response mode is to generate a system reset request. In this case, the state changes to Assert System Reset Request. In response, the reset manager resets and disables the watchdog timer, and gives software the opportunity to reinitialize the timer.

If the `rmod` bit of the `wdt_cr` register is 1, the output response mode is to generate an interrupt. In this case, the state changes to Assert Interrupt and Load Counter with Restart Timeout Value. An interrupt to the processor is generated, and the watchdog counter is reloaded with the restart timeout value. The state then changes to the second Decrement Counter state, and the counter resumes decrementing. If software reads the `wdt_eoi` register, or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to the first Decrement Counter state. If the counter again reaches zero, the state changes to Assert System Reset Request. In response, the reset manager resets the watchdog timer, and gives software the opportunity to reinitialize the timer.

Watchdog Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- L4 Watchdog Module 0
- L4 Watchdog Module 1

Date	Version	Changes
November	2015.11.02	Added note to "Watchdog Timer Counter" section.
May 2015	2015.05.04	Maintenance release.
December 2014	2014.12.15	• Maintenance release. • Added "Taking the Watchdog Timer Out of Reset" section.
June 2014	2014.06.30	• "FPGA Interface" section added • Added address map and register descriptions
February 2014	2014.02.28	Maintenance release.
December 2013	2013.12.30	Minor formatting updates.
November 2012	1.2	Minor updates.
May 2012	1.1	Added programming model and address map and register definitions sections.
January 2012	1.0	Initial release.

Introduction to the HPS Component 25

2015.11.02

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) component is a wrapper that interfaces logic in the user design to the HPS hard logic, simulation models, BFMs, and software handoff files. It instantiates the HPS hard logic in the user design; and enables other soft components to interface with the HPS hard logic. The HPS component itself has a small footprint in the FPGA fabric, because its only purpose is to enable soft logic to connect to the extensive hard logic in the HPS. You can connect soft logic to the HPS.

After the soft logic is connected to the HPS, Qsys ensures the following features:

- Interoperability by adapting Avalon Memory-Mapped (Avalon-MM) interfaces to AXI
- Handle data width mismatches
- Clock domain transfer crossing

This allows you to integrate IP from Altera, 3rd party IP cores, and custom IP cores to the HPS without having to create integration logic.

For a description of the HPS and its integration into the system on a chip (SoC), refer to the *Arria V Device Datasheet* .

For a description of the HPS system architecture and features, refer to the "Introduction to the Hard Processor" and the CoreSight Debug and Trace chapters in volume 3 of the *Arria V Device Handbook*.

For more information about instantiating the HPS component, refer to the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about the HPS component interfaces, refer to the *HPS Component Interfaces* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about simulating the HPS component, refer to the *Simulating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

MPU Subsystem

The MPU subsystem features the dual ARM Cortex-A9 MPCore processors.

Related Information

Cortex-A9 Microprocessor Unit Subsystem on page 9-1

ARM CoreSight Debug Components

The following lists the ARM CoreSight debug components:

- Debug Access Port (DAP)
- System Trace Macrocell (STM)
- Trace Funnel
- Embedded Trace FIFO (ETF)
- AMBA Trace Bus Replicator (Replicator)
- Embedded Trace Router (ETR)
- Trace Port Interface Unit (TPIU)
- Embedded Cross Trigger (ECT)
- Program Trace Macrocell (PTM)

Related Information

CoreSight Debug and Trace on page 10-1

Interconnect

The interconnect consists of the L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The L3 interconnect is an Arteris™ FlexNoC® network-on-chip (NOC) interconnect module.

Related Information

System Interconnect on page 7-1

HPS-to-FPGA Interfaces

The HPS-to-FPGA interfaces provide a variety of communication channels between the HPS and the FPGA fabric. The HPS is highly integrated with the FPGA fabric, resulting in thousands of connecting signals. Some of the HPS-to-FPGA interfaces include:

- FPGA-to-HPS port
- HPS-to-FPGA port
- Lightweight HPS-to-FPGA port
- FPGA-to-SDRAM interface

Related Information

HPS-FPGA Bridges on page 8-1

Memory Controllers

The following lists the memory controller peripherals:

- SDRAM L3 Interconnect
- NAND Flash Controller
- Quad SPI Controller
- SD/MMC Controller

Instantiating the HPS Component 26

2015.11.02

av_5v4 Subscribe Send Feedback

You instantiate the hard processor system (HPS) component in Qsys. The HPS is available in the Qsys IP catalog under **Processor and Peripherals** > **Hard Processor Systems**. This chapter describes the parameters available in the HPS component parameter editor, which opens when you add or edit an HPS component.

Related Information

- **http://www.altera.com/literature/hb/arria-v/av_51002.pdf**
  The HPS requires specific device targets. For a detailed list of supported devices, refer to the *Arria V Device Datasheet* .
- **http://www.altera.com/literature/hb/qts/quartusii_handbook.pdf**
  For general information about using Qsys, refer to the *Creating a System with Qsys* chapter in the *Quartus® II* Handbook.

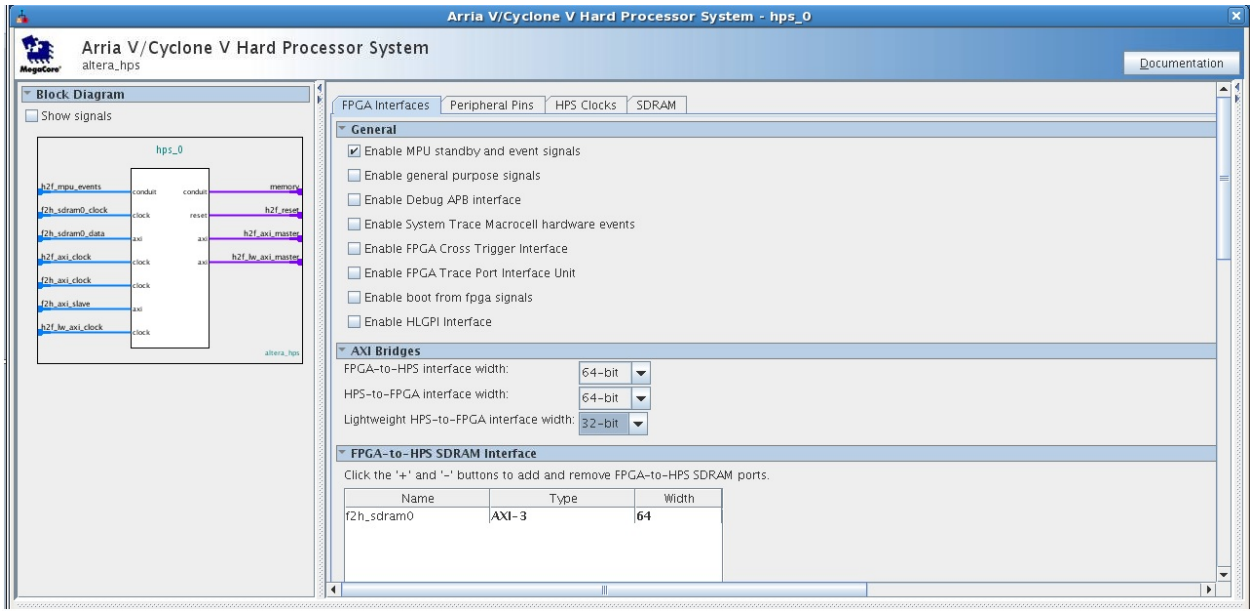
FPGA Interfaces

The **FPGA Interfaces** tab is one of four tabs on the HPS component. This tab contains several groups with the following parameters:

Figure 26-1: FPGA Interface Tab



Related Information

Introduction to the HPS Component on page 25-1

General Interfaces

When enabled, the interfaces described in the following table become visible in the HPS component.

Table 26-1: General Parameters

Parameter Name	Parameter Description	Interface Name
Enable MPU standby and event signals	Enables interfaces that perform the following functions: • Notify the FPGA fabric that the microprocessor unit (MPU) is in standby mode. • "16">Wake up an MPCore processor from a wait for event (WFE) state.	`h2f_mpu_events`

Parameter Name	Parameter Description	Interface Name
Enable general purpose signals	Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA fabric and the FPGA manager in the HPS portion of the SoC device.	`h2f_gp`

Enable Debug APB interface	Enables debug interface to the FPGA, allowing access to debug components in the HPS. For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_debug_apb`
		`h2f_debug_apb_sideband`
		`h2f_debug_apb_clock`
		`h2f_debug_apb_reset`

Enable System Trace Macrocell hardware events	Enables system trace macrocell (STM) hardware events, allowing logic inside the FPGA to insert messages into the trace stream. For more information, refer to the *CoreSight Debug and Trace* chapter.	`f2h_stm_hw_events`
Enable FPGA Cross Trigger interface	Enables the cross trigger interface (CTI), which allows trigger sources and sinks to interface with the embedded cross trigger (ECT). For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_cti` `h2f_cti_clock`

Enable FPGA Trace Port Interface Unit	Enables an interface between the trace port interface unit (TPIU) and logic in the FPGA. The TPIU is a bridge between on-chip trace sources and a trace port. For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_tpiu`
		`h2f_tpiu_clock_in`
		`h2f_tpiu_clock`

Enable boot from FPGA signals	Enables an input to the HPS indicating whether a preloader is available in the on-chip memory of the FPGA. This option also enables a separate input to the HPS indicating a fallback preloader is available in the FPGA memory. A fallback preloader is used when there is no valid preloader image found in flash memory. For more information, refer to *Appendix A: Booting and Configuration*.	`f2h_boot_from_fpga`

Parameter Name	Parameter Description	Interface Name
Enable HLGPI Interface	Enables a general purpose interface that is connected to the General Purpose I/O (GPIO) peripheral of HPS. This is an input-only interface with 14-bit width. This interface shares the I/O pins with the HPS DDR SDRAM controller.	`hps_io (hps_io_gpio_inst_HLGPI[0..13])`

Related Information

- **CoreSight Debug and Trace** on page 10-1
  Enabling the TPIU exposes trace signals to the device pins. Refer to the *CoreSight Debug and Trace* for more information.
- **Booting and Configuration** on page 29-1
  For detailed information about the HPS boot sequence, refer to the *Booting and Configuration*.

FPGA-to-HPS SDRAM Interface

In the **FPGA-to-HPS SDRAM Interface** table, use + or – to add or remove FPGA-to-HPS SDRAM interfaces.

You can add one or more SDRAM ports that make the HPS SDRAM subsystem accessible to the FPGA fabric.

Table 26-2: FPGA-to-HPS SDRAM Port and Interface Names

Port Name	Interface Name
f2h_sdram0	`f2h_sdram0_data` `f2h_sdram0_clock`
f2h_sdram1	`f2h_sdram1_data` `f2h_sdram1_clock`
f2h_sdram2	`f2h_sdram2_data` `f2h_sdram2_clock`
f2h_sdram3	`f2h_sdram3_data` `f2h_sdram3_clock`
f2h_sdram4	`f2h_sdram4_data` `f2h_sdram4_clock`
f2h_sdram5	`f2h_sdram5_data` `f2h_sdram5_clock`

The following table shows the parameters available for each SDRAM interface where the **Name** parameter denotes the interface name.

Table 26-3: FPGA-to-HPS SDRAM Interface Parameters

Parameter Name	Parameter Description
Name	Port name (auto assigned as shown in Table 26-2 table below)
Type	Interface type: • AXI-3 • Avalon-MM Bidirectional • Avalon-MM Write-only • Avalon-MM Read-only
Width	32, 64, 128, or 256

Note: You can configure the slave interface to a data width of 32, 64, 128, or 256 bits. To facilitate accessing this slave from a memory-mapped master with a smaller address width, you can use the *Altera Address Span Extender*.

Related Information

- **Using the Address Span Extender Component** on page 26-15
  Address span extender details
- **SDRAM Controller Subsystem** on page 11-1

DMA Peripheral Request

You can enable each direct memory access (DMA) controller peripheral request ID individually. Each request ID enables an interface for FPGA soft logic to request one of eight logical DMA channels to the FPGA.

Related Information

DMA Controller on page 16-1
For more information, refer to the *DMA Controller* chapter in the *Arria V Device Handbook, Volume 3* .

Interrupts

Table 26-4: FPGA-to-HPS Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable FPGA-to-HPS Interrupts	Enables the interface for FPGA interrupt signals to the MPU (in the HPS).	`f2h_irq0` `f2h_irq1`

You can enable the interfaces for each HPS peripheral interrupt to the FPGA.

Table 26-5: HPS-to-FPGA Interrupts Interface

The following table lists the available HPS-to-FPGA interrupt interfaces and the corresponding parameters to enable them.

Parameter Name	Parameter Description	Interface Name
Enable clock peripheral interrupts	Enables the interface for HPS clock manager and MPU wake-up interrupt signals to the FPGA	`h2f_clkmgr_interrupt` `h2f_mpuwakeup_interrupt`
Enable CTI interrupts	Enables the interface for HPS cross-trigger interrupt signals to the FPGA	`h2f_cti_interrupt0` `h2f_cti_interrupt1`

Enable DMA interrupts	Enables the interface for HPS DMA channels interrupt and DMA abort interrupt to the FPGA	`h2f_dma_interrupt0`
		`h2f_dma_interrupt1`
		`h2f_dma_interrupt2`
		`h2f_dma_interrupt3`
		`h2f_dma_interrupt4`
		`h2f_dma_interrupt5`
		`h2f_dma_interrupt6`
		`h2f_dma_interrupt7`
		`h2f_dma_abort_interrupt`

Enable EMAC interrupts	Enables the interface for HPS Ethernet MAC controller interrupt to the FPGA	`h2f_emac0_interrupt` `h2f_emac1_interrupt`
Enable FPGA manager interrupts	Enables the interface for the HPS FPGA manager interrupt to the FPGA	`h2f_fpga_man_interrupt`

Enable GPIO interrupts	Enables the interface for the HPS general purpose IO (GPIO) interrupt to the FPGA	`h2f_gpio0_interrupt`
		`h2f_gpio1_interrupt`
		`h2f_gpio2_interrupt`

Enable I^2C-EMAC interrupts (for I2C2 and I2C3)	Enables the interface for the HPS I^2C interrupt to the FPGA (I^2C used for EMAC media interface control)	`h2f_i2c_emac0_interrupt` `h2f_i2c_emac1_interrupt`
Enable I^2C peripheral interrupts (for I2C0 and I2C1)	Enables the interface for the HPS I^2C interrupt to the FPGA (I^2C used for general purpose)	`h2f_i2c0 _interrupt` `h2f_i2c1_interrupt`

Parameter Name	Parameter Description	Interface Name
Enable L4 timer interrupts	Enables interface for the HPS SP timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the *Timer* chapter in the *Arria V Device Handbook, Volume 3*.	`h2f_l4sp0_interrupt` `h2f_l4sp1_interrupt`
Enable NAND interrupts	Enables the interface for the HPS NAND controller interrupt to the FPGA	`h2f_nand_interrupt`
Enable OSC timer interrupts	Enables the interface for the HPS OSC timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the *Timer* chapter in the *Arria V Device Handbook, Volume 3*.	`h2f_osc0_interrupt` `h2f_osc1_interrupt`
Enable Quad SPI interrupts	Enables interface for the HPS QSPI controller interrupt to the FPGA	`h2f_qspi_interrupt`
Enable SD/MMC interrupts	Enables the interface for the HPS SD/MMC controller interrupt to the FPGA	`h2f_sdmmc_interrupt`
Enable SPI master interrupts	Enables the interface for the HPS SPI master controller interrupt to the FPGA	`h2f_spi0_interrupt` `h2f_spi1_interrupt`
Enable SPI slave interrupts	Enablesthe interface for the HPS SPI slave controller interrupt to the FPGA	`h2f_spi2_interrupt` `h2f_spi3_interrupt`
Enable UART interrupts	Enables the interface for the HPS UART controller interrupt to the FPGA	`h2f_uart0_interrupt` `h2f_uart1_interrupt`
Enable USB interrupts	Enables the interface for the HPS USB controller interrupt to the FPGA	`h2f_usb0_interrupt` `h2f_usb1_interrupt`
Enable watchdog interrupts	Enables the interface for the HPS watchdog interrupt to the FPGA	`h2f_wdog0_interrupt` `h2f_wdog1_interrupt`

AXI Bridges

Table 26-6: Bridge Parameters

Parameter Name	Parameter Description	Interface Name
FPGA-to-HPS interface width	Enable or disable the FPGA-to-HPS interface; if enabled, set the data width to 32, 64, or 128 bits.	`f2h_axi_slave` `f2h_axi_clock`
HPS-to-FPGA interface width	Enable or disable the HPS-to-FPGA interface; if enabled, set the data width to 32, 64, or 128 bits.	`h2f_axi_master` `h2f_axi_clock`
Lightweight HPS-to-FPGA interface width	Enable or disable the lightweight HPS-to-FPGA interface. When enabled, the data width is 32 bits.	`h2f_lw_axi_master` `h2f_lw_axi_clock`

Note: To facilitate accessing these slaves from a memory-mapped master with a smaller address width, you can use the Altera Address Span Extender.

Configuring HPS Clocks and Resets

The **HPS Clocks** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

#unique_2902

User Clocks on page 26-8

Reset Interfaces on page 26-9

PLL Reference Clocks on page 26-10

Peripheral FPGA Clocks on page 26-11

User Clocks

When you enable a HPS-to-FPGA user clock, you must manually enter its maximum frequency for timing analysis. The TimeQuest Timing Analyzer has no other information about how software running on the HPS configures the phase-locked loop (PLL) outputs. Each possible clock, including clocks that are available from peripherals, has its own parameter for describing the clock frequency.

Related Information

Selecting PLL Output Frequency and Phase on page 26-15

User Clock Parameters

The frequencies that you provide are the maximum expected frequencies. The actual clock frequencies can be modified through the register interface, for example by software running on the microprocessor unit (MPU). For further details, refer to *Selecting PLL Output Frequency and Phase*.

Table 26-7: User Clock Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 0 clock	Enable main PLL from HPS-to-FPGA	`h2f_user0_clock`
User 0 clock frequency	Specify the maximum expected frequency for the main PLL	
Enable HPS-to-FPGA user 1 clock	Enable peripheral PLL from HPS-to-FPGA	`h2f_user1_clock`
User 1 clock frequency	Specify the maximum expected frequency for the peripheral PLL	
Enable HPS-to-FPGA user 2 clock	Enable SDRAM PLL from HPS-to-FPGA	`h2f_user2_clock`
User 2 clock frequency	Specify the maximum expected frequency for the SDRAM PLL	

Related Information

Selecting PLL Output Frequency and Phase on page 26-15

Clock Frequency Usage

The clock frequencies you provide are reported in a Synopsys Design Constraints File (**.sdc**) generated by Qsys. The **.sdc** file will be referenced in the system **.qip** file when the system is generated.

Related Information

- **Selecting PLL Output Frequency and Phase** on page 26-15
- **Clock Manager** on page 2-1
  For general information about clock signals, refer to the *Clock Manager* chapter in the *Arria V Device Handbook, Volume 3* .

Reset Interfaces

You can enable the resets on an individual basis through the **FPGA Interfaces** tab under the **Resets** section.

Table 26-8: Reset Parameters

Parameter Name	Parameter Description	Interface Name
Enable HPS-to-FPGA cold reset output	Enable interface for HPS-to-FPGA cold reset output	`h2f_cold_reset`
Enable HPS warm reset handshake signals	Enable an additional pair of reset handshake signals allowing soft logic to notify the HPS when it is safe to initiate a warm reset in the FPGA fabric.	`h2f_warm_reset_handshake`
Enable FPGA-to-HPS debug reset request	Enable interface for FPGA-to-HPS debug reset request	`f2h_debug_reset_req`
Enable FPGA-to-HPS warm reset request	Enable interface for FPGA-to-HPS warm reset request	`f2h_warm_reset_req`
Enable FPGA-to-HPS cold reset request	Enable interface for FPGA-to-HPS cold reset request	`f2h_cold_reset_req`

Related Information

Reset Manager on page 3-1
For more information about the reset interfaces, refer to *Functional Description of the Reset Manager* in the *Reset Manager* chapter in the *Arria V Device Handbook, Volume 3* .

PLL Reference Clocks

Table 26-9: PLL Reference Clock Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable FPGA-to-HPS peripheral PLL reference clock	Enable the interface for FPGA fabric to supply reference clock to HPS peripheral PLL	`f2h_periph_ref_clock`
Enable FPGA-to-HPS SDRAM PLL reference clock	Enable the interface for FPGA fabric to supply reference clock to HPS SDRAM PLL	`f2h_sdram_ref_clock`

Related Information

Clock Manager on page 2-1
For general information about clock signals, refer to the *Clock Manager* chapter in the *Arria V Device Handbook, Volume 3* .

Peripheral FPGA Clocks

Table 26-10: Peripheral FPGA Clock Parameters

Parameter Name	Parameter Description
EMAC 0 (emac0_md_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 MDIO clock frequency
EMAC 0 (emac0_gtx_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 transmit clock frequency
EMAC 1 (emac1_md_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 MDIO clock frequency
EMAC 1 (emac1_gtx_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 transmit clock frequency
QSPI (qspi_sclk_out clock frequency)	If QSPI peripheral is routed to FPGA, use the input field to specify QSPI serial clock frequency
SPIM 0 (spim0_sclk_out clock frequency)	If SPI master 0 peripheral is routed to FPGA, use the input field to specify SPI master 0 output clock frequency
SPIM 1 (spim1_sclk_out clock frequency)	If SPI master 1 peripheral is routed to FPGA, use the input field to specify SPI master 1 output clock frequency
I^2C0 (i2c0_clk clock frequency)	If I^2C 0 peripheral is routed to FPGA, use the input field to specify I^2C 0 output clock frequency
I^2C1 (i2c1_clk clock frequency)	If I^2C 1 peripheral is routed to FPGA, use the input field to specify I^2C 1 output clock frequency
I^2C2 (i2c2_clk clock frequency)	If I^2C 2 peripheral is routed to FPGA, use the input field to specify I^2C 2 output clock frequency
I^2C3 (i2c3_clk clock frequency)	If I^2C 3 peripheral is routed to FPGA, use the input field to specify I^2C 3 output clock frequency

Configuring Peripheral Pin Multiplexing

The **Peripheral Pin Multiplexing** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

Configuring Peripherals on page 26-12

Connecting Unassigned Pins to GPIO on page 26-12

Using Unassigned IO as LoanIO on page 26-12
You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional IO.

Resolving Pin Multiplexing Conflicts on page 26-13
Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

Peripheral Signals Routed to FPGA on page 26-13

Configuring Peripherals

The **Peripheral Pin Multiplexing** tab contains a group of parameters for each available type of peripheral. You can enable one or more instances of each peripheral type by selecting an HPS I/O pin set for each instance. When enabled, some peripherals also have mode settings specific to their functions.

When you assign a peripheral to an HPS I/O pin set, the corresponding peripheral is highlighted in the **Peripherals MUX Table** at the end of **Peripheral Pin Multiplexing** tab. The other unused peripheral pin set remains un-highlighted in the table.

Each list in the **Peripheral Pin Multiplexing** tab has a hint describing in detail the options available in the list. The hint for each mode list shows the signals used by each available mode. View each hint by hovering over the corresponding mode list.

You can enable the following types of peripherals. For details of peripheral-specific settings, refer to the chapter for each peripheral:

Related Information

- **I2C Controller** on page 20-1
- **UART Controller** on page 21-1

Connecting Unassigned Pins to GPIO

For pins that are not assigned to any peripherals, you can assign them to the GPIO peripheral by clicking on the corresponding GPIO push button in the table. Click on the selected push button to remove GPIO pin assignment. The table also shows the GPIO bit number that correlates to the I/O pins.

Using Unassigned IO as LoanIO

You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional IO.

Each LOANIO port has an input, output, and output enable, which directly controls the HPS IO functions. The LoanIO only operates when the HPS registers have been set up in the pre-loader to allow their operation. The LoanIO are asynchronous, thus no clocking is required.

The status of LOAN_IO in the duration after HPS I/O is configured and before the FPGA is configured is as follows: When the FPGA powers up and is "not" configured, inputs into the HPS from the FPGA are driven to a logical 1. When the FPGA is configured the signal may toggle, and then will take on whatever level the FPGA user design drives out.

Use the following steps to enable the LoanIO signals:

1. Select the **Peripheral Pins Multiplexing** tab in the HPS Megawizard.
2. Choose the corresponding LoanIO pins from the **Peripherals Mux Table**, and click the push button to select/unselect it.
3. Export the peripheral signals out of the Qsys system.
4. In the Quartus II software, connect the user logic to the LoanIO interface to drive the HPS IOs.

Table 26-11: Generated Conduit Signal Interface

Conduit Name	Direction	Declarations
._hps_io_gpio_inst_LOANIOXX	Bi-direction	User must declare as a top-level pin; pin assignment is hardcoded following the HPS IO location.
._h2f_loan_io_in	Out	HPS IO data input signal, output to FPGA user logic.
._h2f_loan_io_out	In	HPS IO data output signal, input from FPGA user logic.
._h2f_loan_io_oe	In	HPS IO data output enable signal, input from FPGA user logic.

Qsys will generate a full signal array for `h2f_loan_io_in, h2f_loan_io_out`, and `h2f_loan_io_oe`. You must assign user logic to the specific signal array. For example, you have triggered LoanIO 40, so its respective signal array is `h2f_loan_io_in[40], h2f_loan_io_out[40]`, and `h2f_loan_io_oe[40]`.

Resolving Pin Multiplexing Conflicts

Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

Pins that have multiple peripherals assigned to them are highlighted in red color with the conflicting peripherals in boldface font style. Solve the multiplexing conflicts by de-selecting peripherals that are assigned to the pins, leaving only one peripheral, which is needed.

Peripheral Signals Routed to FPGA

You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

The following steps show you how to enable the peripheral signals:

1. Select FPGA in the peripheral pin multiplexing selection drop-down box.
2. Export the peripheral signals out of Qsys system.
3. In the software, connect the signals to the FPGA I/O pins.

Note: When routed to the FPGA, some HPS peripherals require additional pipeline support in the connected soft logic. Routing into the FPGA circumvents the pipelining available in the HPS I/O. Refer to the relevant HPS peripheral chapter for details.

Configuring the External Memory Interface

The **SDRAM** tab is one of four tabs on the HPS component. This tab contains the PLL output frequency and phase group.

The HPS supports one memory interface implementing double data rate 2 (DDR2), double data rate 3 (DDR3), and low-power double data rate 2 (LPDDR2) protocols. The interface can be up to 40 bits wide with optional error correction code (ECC).

Configuring the HPS SDRAM controller is similar to configuring any other Altera SDRAM controller. There are several important differences:

- The HPS parameter editor supports all SDRAM protocols with one tab. When you parameterize the SDRAM controller, you must specify the memory protocol: DDR2, DDR3, or LPDDR2.

To select the memory protocol, select DDR2, DDR3, or LPDDR2 from the **SDRAM Protocol** list in the **SDRAM** tab. After you select the protocol, settings not applicable to that protocol are disabled.

- Many HPS SDRAM controller settings are the same as for Altera's dedicated DDR2, DDR3, and LPDDR2 controllers. This section only describes SDRAM parameters that are specific to the HPS component.
- Because the HPS memory controller is not configurable through the Quartus II software, the Controller and Diagnostic tabs are not present in the HPS parameter editor.
- Some settings, such as the controller settings, are not included because they can only be configured through the register interface, for example by software running on the MPU.
- Unlike the memory interface clocks in the FPGA, the memory interface clocks for the HPS are initialized by the boot-up code using values provided by the configuration process. You can accept the values provided by UniPHY, or you can use your own PLL settings, as described in *Selecting PLL Output Frequency and Phase*.

Note: The HPS does not support external memory interface (EMIF) synthesis generation, compilation, or timing analysis.

The HPS memory controller cannot be bonded with a memory controller on the FPGA portion of the device.

For detailed information about SDRAM controller parameters, refer to the following chapters:

Selecting PLL Output Frequency and Phase

You select PLL output frequency and phase with controls in the **PHY Settings** tab. In the HPS, PLL frequencies and phases are set by software at system startup. A PLL might not be able to produce the exact frequency that you specify in **Memory clock frequency**. Normally, the Quartus II software sets **Achieved memory clock frequency** to the closest achievable frequency, using an algorithm that tries to balance frequency accuracy against clock jitter. This clock frequency is used for timing analysis by the TimeQuest analyzer.

It is possible to use a different software algorithm for configuring the PLLs. You can force the **Achieved memory clock frequency** box to take on the same value as **Memory clock frequency**, by turning on **Use specified frequency instead of calculated frequency** in the **PHY Settings** tab, under **Clocks**.

Note: If you turn on **Use specified frequency instead of calculated frequency**, the Quartus II software assumes that the value in the **Achieved memory clock frequency** box is correct. If it is not, timing analysis results are incorrect.

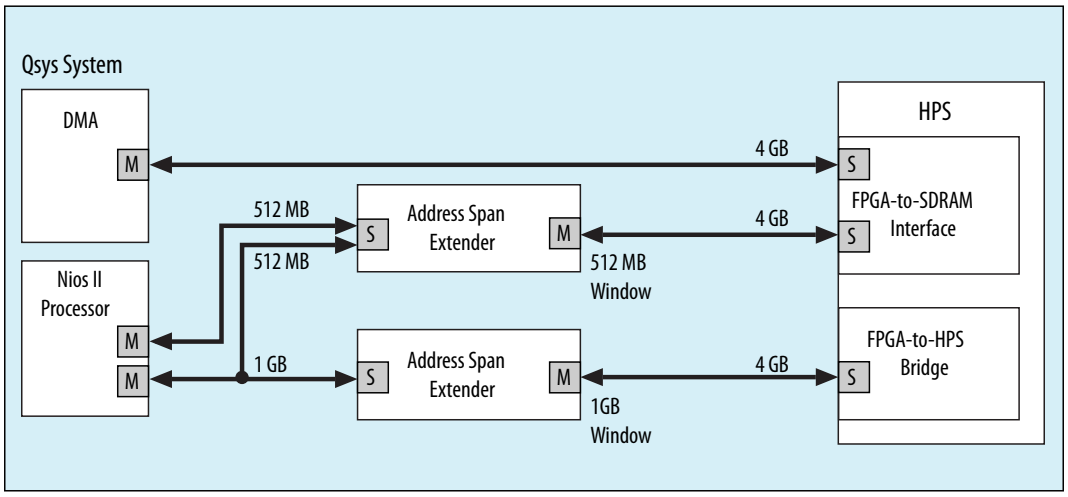
Using the Address Span Extender Component

The FPGA-to-HPS bridge and FPGA-to-HPS SDRAM memory-mapped interfaces expose their entire 4-GB address spaces to the FPGA fabric. The address span extender component provides a memory-mapped window into the address space that it masters. Using the address span extender, you can expose portions of the HPS memory space without needing to expose the entire 4 GB address space.

You can use the address span extender between a soft logic master and an FPGA-to-HPS bridge or FPGA-to-HPS SDRAM interface. This component reduces the number of address bits required for a master to address a memory-mapped slave interface located in the HPS.

Figure 26-2: Address Span Extender Components

Two address span extender components used in a system with the HPS.



You can also use the address span extender in the HPS-to-FPGA direction, for slave interfaces in the FPGA. In this case, the HPS-to-FPGA bridge exposes a limited, variable address space in the FPGA, which can be paged in using the address span extender.

For example, suppose that the HPS-to-FPGA bridge has a 1-GB span, and the HPS needs to access three independent 1-GB memories in the FPGA portion of the device. To achieve this, the HPS programs the address span extender to access one SDRAM (1-GB) in the FPGA at a time. This technique is commonly called paging or windowing.

Related Information

  For more information about the address span extender, refer to *Bridges* in the *Qsys* Interconnect and System Design Components chapter in the *Quartus® II* Handbook.

Generating and Compiling the HPS Component

The process of generating and compiling an HPS design is very similar to the process for any other Qsys project. Perform the following steps:

1. Generate the design with Qsys. The generated files include an **.sdc** file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add *<qsys_system_name>.qip* to the Quartus II project. *<qsys_system_name>.qip* is the Quartus II IP file for the HPS component, generated by Qsys.
3. Perform analysis and synthesis with the Quartus II software.
4. Assign constraints to the SDRAM component. When Qsys generates the HPS component (step 1), it generates the pin assignment Tcl Script File (**.tcl**) to perform memory assignments. The script file

name is **<qsys_system_name>_pin_assignments.tcl**, where <qsys_system_name> is the name of your Qsys system. Run this script to assign constraints to the SDRAM component.

Note: For information about running the pin assignment script, refer to "IP catalog" in the *Implementing and* Parameterizing Memory IP chapter in the *External Memory Interface Handbook*.

You do not need to specify pin assignments other than memory assignments. When you configure pin multiplexing as described in *Configuring Peripheral Pin Multiplexing* section, you implicitly make pin assignments for all HPS peripherals. Each peripheral is routed exclusively to the pins you specify. HPS I/O signals are exported to the top level of the Qsys design, with information enabling the Quartus II software to make pin assignments automatically.

You can view and modify the assignments in the **Peripheral Pin Multiplexing** tab. You can also view the assignments in the Quartus fitter report.

5. Compile the design with the Quartus II software.
6. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

1. Generate the design with Qsys. The generated files include an **.sdc** file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add *<qsys_system_name>.qip* to the Quartus II project. *<qsys_system_name>.qip* is the Quartus II IP File for the HPS component, generated by Qsys.

   Note: Qsys generates pin assignments in the **qip** file.
3. Perform analysis and synthesis with the Quartus II software.
4. Compile the design with the Quartus II software.
5. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

Document Revision History

Table 26-12: Document Revision History

Date	Version	Changes
November 2015	2015.11.02	Updated Sections: • Configuring Peripherals • Peripheral Signals Routed to FPGA
May 2015	2015.05.04	Maintenance release.
December 2014	2014.12.15	Maintenance release.
June 2014	2014.06.30	• Updated the "Instantiating the HPS Component" section. • Added the "Using Unassigned I/O as Loan I/O" section. • Removed reference to CAN interrupts from the "Interrupts" section.
February 2014	2014.02.28	• Add interfaces to tables • Add parameters to General Parameters table
December 2013	1.2	Maintenance release.
November 2012	1.1	• Added debug interfaces • Added boot options • Corrected slave address width • Corrected SDRAM interface widths • Added TPIU peripheral • Added .sdc file generation • Added .tcl script for memory assignments
June 2012	1.0	Initial release.
May 2012	0.1	Preliminary draft.

HPS Component Interfaces 27

2015.11.02

av_5v4 Subscribe Send Feedback

This chapter describes the interfaces, including clocks and resets, implemented by the hard processor system (HPS) component.

The majority of the resets can be enabled on an individual basis. The exception is the `h2f_reset` interface, which is always enabled.

You must declare the clock frequency of each HPS-to-FPGA clock for timing purposes. Each possible clock, including ones that are available from peripherals, has its own parameter for describing the clock frequency. Declaring the clock frequency for HPS-to-FPGA clocks specifies how you plan to configure the PLLs and peripherals, to enable TimeQuest to accurately estimate system timing. It has no effect on PLL settings.

ISO 9001:2008 Registered

The FPGA-to-HPS interface is a configurable data width AXI slave allowing FPGA masters to issue transactions to the HPS. This interface allows the FPGA fabric to access the majority of the HPS slaves. This interface also provides a coherent memory interface.

The FPGA-to-HPS interface is an AXI-3 compliant interface with the following features:

- Configurable data width: 32, 64, or 128 bits
- Accelerator Coherency Port (ACP) sideband signals
- HPS-side AXI bridge to manage clock crossing, buffering, and data width conversion

Other interface standards in the FPGA fabric, such as connecting to Avalon® Memory-Mapped (Avalon-MM) interfaces, can be supported through the use of soft logic adapters. The Qsys system integration tool automatically generates adapter logic to connect AXI to Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Altera® Address Span Extender.

ACP Sideband Signals

For communication with the ACP on the microprocessor unit (MPU) subsystem, AXI sideband signals are used to describe the inner cacheable attributes for the transaction.

Related Information

Cortex-A9 MPCore on page 9-4
For more information about the ACP sideband signals, refer to the *Cortex-A9 MPU Subsystem* chapter.

HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges

Table 27-2: HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges and Clocks

Interface Name	Description	Associated Clock Interface
`h2f_axi_master`	HPS-to-FPGA AXI master interface	`h2f_axi_clock`
`h2f_lw_axi_master`	HPS-to-FPGA lightweight AXI master interface	`h2f_lw_axi_clock`

The HPS-to-FPGA interface is a configurable data width AXI master (32-, 64-, or 128-bit) that allows HPS masters to issue transactions to the FPGA fabric.

The lightweight HPS-to-FPGA interface is a 32-bit AXI master that allows HPS masters to issue transactions to the FPGA fabric.

Both HPS-to-FPGA interfaces are AXI-3 compliant. The HPS-side AXI bridges manage clock crossing, buffering, and data width conversion where necessary.

Other interface standards in the FPGA fabric, such as connecting to Avalon-MM interfaces, can be supported through the use of soft logic adaptors. The Qsys system integration tool automatically generates adaptor logic to connect AXI to Avalon-MM interfaces.

Each AXI bridge accepts a clock input from the FPGA fabric and performs clock domain crossing internally. The exposed AXI interface operates on the same clock domain as the clock supplied by the FPGA fabric.

Related Information

  For more information, refer to the *HPS FPGA AXI Bridges Component* chapter.

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface is a direct connection between the FPGA fabric and the HPS SDRAM controller. This interface is highly configurable, allowing a mix between number of ports and port width. The interface supports both AXI-3 and Avalon-MM protocols.

Table 27-3: FPGA-to-HPS SDRAM Interfaces and Clocks

Interface Name	Description	Associated Clock Interface
`f2h_sdram0_data`	SDRAM AXI or Avalon-MM port 0	`f2h_sdram0_clock`
`f2h_sdram1_data`	SDRAM AXI or Avalon-MM port 1	`f2h_sdram1_clock`
`f2h_sdram2_data`	SDRAM AXI or Avalon-MM port 2	`f2h_sdram2_clock`
`f2h_sdram3_data`	SDRAM AXI or Avalon-MM port 3	`f2h_sdram3_clock`
`f2h_sdram4_data`	SDRAM AXI or Avalon-MM port 4	`f2h_sdram4_clock`
`f2h_sdram5_data`	SDRAM AXI or Avalon-MM port 5	`f2h_sdram5_clock`

The FPGA-to-HPS SDRAM interface is a configurable interface to the multi-port SDRAM controller.

The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction. The interface is implemented as four 64-bit read ports and four 64-bit write ports. As a result, the minimum data width used by the interface is 64 bits, regardless of the number or type of interfaces.

You can configure this interface the following ways:

- AXI-3 or Avalon-MM protocol
- Number of interfaces
- Data width of interfaces

The FPGA-to-HPS SDRAM interface supports six command ports, allowing up to six Avalon-MM interfaces or three bidirectional AXI interfaces.

Each command port is available either to implement a read or write command port for AXI, or to form part of an Avalon-MM interface.

You can use a mix of Avalon-MM and AXI interfaces, limited by the number of command/data ports available. Some AXI features are not present in Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Altera Address Span Extender.

Note: If you connect the HPS-to-SDRAM interface with the Avalon MM pipeline bridge, you will to set the bridge **Addressing Unit** setting to **Word**.

Clocks

The HPS-to-FPGA clock interface supplies physical clocks to the FPGA. These clocks and resets are generated in the HPS.

Alternative Clock Inputs to HPS PLLs

This section lists alternative clock inputs to HPS PLLs.

- `f2h_periph_ref_clock`—FPGA-to-HPS peripheral PLL reference clock. You can connect this clock input to a clock in your design that is driven by the clock network on the FPGA side.
- `f2h_sdram_ref_clock`—FPGA-to-HPS SDRAM PLL reference clock. You can connect this clock to a clock in your design that is driven by the clock network on the FPGA side.

User Clocks

A user clock is a PLL output that is connected to the FPGA fabric rather than the HPS. You can connect a user clock to logic that you instantiate in the FPGA fabric.

- `h2f_user0_clock`—HPS-to-FPGA user clock, driven from main PLL
- `h2f_user1_clock`—HPS-to-FPGA user clock, driven from peripheral PLL
- `h2f_user2_clock`—HPS-to-FPGA user clock, driven from SDRAM PLL

Note: At power-up or reset, when `CSEL[3:0]`=0x0 or `BSEL[2:0]` is configured to boot from FPGA, the HPS PLLs are in bypass mode. Thus, HPS user clocks exported to the FPGA fabric run at `osc1_clk` frequency. For more information refer to the *Clock Selection* section.

Related Information

Clock Select on page 29-25
The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

AXI Bridge FPGA Interface Clocks

The AXI interface has an asynchronous clock crossing in the FPGA-to-HPS bridge. The FPGA-to-HPS and HPS-to-FPGA interfaces are synchronized to clocks generated in the FPGA fabric. These interfaces can be asynchronous to one another. The SDRAM controller's multiport front end (MPFE) transfers the data between the FPGA and HPS clock domains.

- `f2h_axi_clock`—AXI slave clock for FPGA-to-HPS bridge, generated in FPGA fabric
- `h2f_axi_clock`—AXI master clock for HPS-to-FPGA bridge, generated in FPGA fabric
- `h2f_lw_axi_clock`—AXI master clock for lightweight HPS-to-FPGA bridge, generated in FPGA fabric

SDRAM Clocks

You can configure the HPS component with up to six FPGA-to-HPS SDRAM clocks.

Each command channel to the SDRAM controller has an individual clock source from the FPGA fabric. The interface clock is always supplied by the FPGA fabric, with clock crossing occurring on the HPS side of the boundary.

The FPGA-to-HPS SDRAM clocks are driven by soft logic in the FPGA fabric.

- `f2h_sdram0_clock`—SDRAM clock for port 0
- `f2h_sdram1_clock`—SDRAM clock for port 1
- `f2h_sdram2_clock`—SDRAM clock for port 2
- `f2h_sdram3_clock`—SDRAM clock for port 3
- `f2h_sdram4_clock`—SDRAM clock for port 4
- `f2h_sdram5_clock`—SDRAM clock for port 5

Peripheral FPGA Clocks

The HPS peripheral clocks are exposed when the peripheral signals are routed to the FPGA.

Table 27-4: Peripheral FPGA Clocks

Clock Name	Description
`emac_md_clk`	Ethernet PHY management interface clock
`emac_gtx_clk`	Ethernet transmit clock that is used by the PHY in GMII mode
`emac_rx_clk_in`	Ethernet MAC reference clock from the PHY
`emac_tx_clk_in`	Ethernet MAC uses this clock input for TX reference

Clock Name	Description
emac_ptp_ref_clock	Ethernet timestamp precision time protocol (PTP) reference clock
qspi_sclk_out	QSPI master clock output
spim_sclk_out	SPI master serial clock output
spis_sclk_in	SPI slave serial clock input
i2c_clk	I^2C outgoing clock (part of the SCL bidirectional pin signals)
i2c_scl_in	I^2C incoming clock (part of the SCL bidirectional pin signals)

Resets

This section describes the reset interfaces to the HPS component.

Related Information

Reset Manager on page 3-1
For details about the HPS reset sequences, refer to the *Functional Description of the Reset Manager* in the *Reset Manager* chapter .

HPS-to-FPGA Reset Interfaces

The following interfaces allow the HPS to reset soft logic in the FPGA fabric:

- h2f_reset—HPS-to-FPGA warm reset
- h2f_cold_reset—HPS-to-FPGA cold reset
- h2f_warm_reset_handshake—Warm reset request and acknowledge interface between HPS and FPGA

HPS External Reset Request

The following interfaces allow soft logic in the FPGA fabric to request for different types of HPS resets:

- f2h_cold_reset_req—FPGA-to-HPS cold reset request
- f2h_warm_reset_req—FPGA-to-HPS warm reset request
- f2h_dbg_reset_req—FPGA-to-HPS debug reset request

Peripheral Reset Interfaces

The following are Ethernet reset interfaces, that can be used when the Ethernet is routed to the FPGA:

- emac_tx_reset— Ethernet transmit clock reset output used to reset external PHY TX clock domain logic
- emac_rx_reset— Ethernet receive clock reset output used to reset external PHY RX clock domain logic

Debug and Trace Interfaces

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and a trace port.

- `h2f_tpiu`
- `h2f_tpiu_clock_in`
- `h2f_tpiu_clock`

FPGA System Trace Macrocell Events Interface

The system trace macrocell (STM) hardware events allow logic in the FPGA to insert messages into the trace stream.

- `f2h_stm_hw_events`

FPGA Cross Trigger Interface

The cross trigger interface (CTI) allows trigger sources and sinks to interface with the embedded cross trigger (ECT).

- `h2f_cti`
- `h2f_cti_clock`

Debug APB Interface

The debug Advanced Peripheral Bus (APB™) interface allows debug components in the FPGA fabric to debug components on the CoreSight™ debug APB.

- `h2f_debug_apb`
- `h2f_debug_apb_sideband`
- `h2f_debug_apb_reset`
- `h2f_debug_apb_clock`

Peripheral Signal Interfaces

DMA Controller Interface

The DMA controller interface allows soft IP in the FPGA fabric to communicate with the DMA controller in the HPS. You can configure up to eight separate interface channels.

- `f2h_dma_req0`—FPGA DMA controller peripheral request interface 0
- `f2h_dma_req1`—FPGA DMA controller peripheral request interface 1
- `f2h_dma_req2`—FPGA DMA controller peripheral request interface 2
- `f2h_dma_req3`—FPGA DMA controller peripheral request interface 3
- `f2h_dma_req4`—FPGA DMA controller peripheral request interface 4
- `f2h_dma_req5`—FPGA DMA controller peripheral request interface 5
- `f2h_dma_req6`—FPGA DMA controller peripheral request interface 6
- `f2h_dma_req7`—FPGA DMA controller peripheral request interface 7

Each of the DMA peripheral request interface contains the following three signals:

- `f2h_dma_req`—This signal is used to request burst transfer using the DMA
- `f2h_dma_single`—This signal is used to request single word transfer using the DMA
- `f2h_dma_ack`—This signal indicates the DMA acknowledgment upon requests from the FPGA

Related Information

DMA Controller on page 16-1
For details about the DMA Controller, refer to *DMA controller* chapter.

Other Interfaces

Related Information

Cortex-A9 MPCore on page 9-4
For more information, refer to *Cortex-A9 MPU Subsystem* .

MPU Standby and Event Interfaces

MPU standby signals are notification signals to the FPGA fabric that the MPU is in standby. Event signals are used to wake up the Cortex-A9 processors from a wait for event (WFE) state. The following shows the signals in the interface:

- `h2f_mpu_events`—MPU standby and event interface, including the following signals.
- `h2f_mpu_eventi`—Sends an event from logic in the FPGA fabric to the MPU. This FPGA-to-HPS signal is used to wake up a processor that is in a Wait For Event state. Asserting this signal has the same effect as executing the `SEV` instruction in the Cortex-A9. This signal must be de-asserted until the FPGA fabric is powered-up and configured.
- `h2f_mpu_evento`—Sends an event from the MPU to logic in the FPGA fabric. This HPS-to-FPGA signal is asserted when an SEV instruction is executed by one of the Cortex-A9 processors.
- `h2f_mpu_standbywfe[1:0]`—Indicates which Cortex-A9 processor is in the WFE state
- `h2f_mpu_standbywfi[1:0]`—Indicates which Cortex-A9 processor is in the wait for interrupt (WFI) state

The MPU provides signals to indicate when it is in a standby state. These signals are available to custom hardware designs in the FPGA fabric.

Related Information

Cortex-A9 MPCore on page 9-4
For more information, refer to *Cortex-A9 MPU Subsystem* .

General Purpose Signals

`h2f_mpu_gp`—General purpose interface

FPGA-to-HPS Interrupts

You can configure the HPS component to provide 64 general purpose FPGA-to-HPS interrupts, allowing soft IP in the FPGA fabric to trigger interrupts to the MPU's generic interrupt controller (GIC). The interrupts are implemented through the following 32-bit interfaces:

- `f2h_irq0`—FPGA-to-HPS interrupts 0 through 31
- `f2h_irq1`—FPGA-to-HPS interrupts 32 through 63

The FPGA-to-HPS interrupts are asynchronous on the FPGA interface. Inside the HPS, the interrupts are synchronized to the MPU's internal peripheral clock (`periphclk`).

Related Information

HPS Component Interfaces on page 27-1
There are various HPS peripherals to FPGA interrupt interfaces that you can configure. To learn the complete list of interfaces, refer to the *Instantiating the HPS Component* chapter.

Boot from FPGA Interface

You can enable the boot from FPGA interface to indicate the availability of preloader software in the FPGA memory. This interface is used to indicate the availability of a fallback preloader software in FPGA memory as well. The fallback preloader is used when there is no valid preloader image found in HPS flash memories.

Input-only General Purpose Interface

You can enable a general purpose interface that is connected to the general purpose I/O (GPIO) peripheral of the HPS. This is an input-only interface with 14-bit wide width. The interface share the same I/O pins with the HPS DDR SDRAM controller.

Document Revision History

Table 27-5: Document Revision History

Date	Version	Changes
November 2015	2015.11.02	Maintenance release.
May 2015	2015.05.04	• Added note to FGPA-to-HPS SDRAM Interface section • Added note to User Clocks section
December 2014	2014.12.15	User Clock 2 has been removed
	2014.06.30	Added address map and register descriptions

Date	Version	Changes
February 2014	2014.02.28	Added sections: • Peripheral FPGA Clocks • Peripheral Reset Interfaces • Boot from FPGA Interface • Input-only General Purpose Interfaces Removed section: • General Purpose Interfaces Updated sections: • Trace Port Interface Unit • Peripheral Signal Interfaces • FPGA-to-HPS Interrupts
December 2013	2013.12.30	Minor formatting issues
November 2012	1.1	• Added debug interfaces. • Updated HPS-to-FPGA reset interface names. • Updated HPS external reset source interface names. • Removed DMA peripheral interface clocks. • Referred to Altera Address Span Extender.
June 2012	1.0	Initial release.
May 2012	0.1	Preliminary draft.

Simulating the HPS Component 28

2015.11.02

av_5v4 Subscribe Send Feedback

This section describes the simulation support for the hard processor system (HPS) component. The HPS simulation models provide bus functional models of the HPS and FPGA fabric and a simulation model of the interface to SDRAM memory.

The HPS simulation support does not include modules implemented in the HPS, such as the ARM Cortex-A9 MPCore processor.

The simulation support files are specified when the HPS component is instantiated in the Qsys system integration tool. When you enable a particular HPS-FPGA interface, Qsys provides the corresponding model during the generation process.

The HPS simulation support enables you to develop and verify your own FPGA user logic or intellectual property (IP) that interfaces to the HPS component.

The simulation model supports the following interfaces:

- Clock and reset interfaces
- FPGA-to-HPS Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) slave interface
- HPS-to-FPGA AXI master interface
- Lightweight HPS-to-FPGA AXI master interface
- FPGA-to-HPS SDRAM interface
- Microprocessor unit (MPU) general-purpose I/O (GPIO) interface
- MPU standby and event interface
- Interrupts interface
- Direct memory access (DMA) controller peripheral request interface
- Debug Advanced Peripheral Bus (APB) interface
- System Trace Macrocell (STM) hardware event
- FPGA cross trigger interface (CTI)
- FPGA trace port interface unit (TPIU)
- Boot from FPGA interface
- Input-only general purpose interface

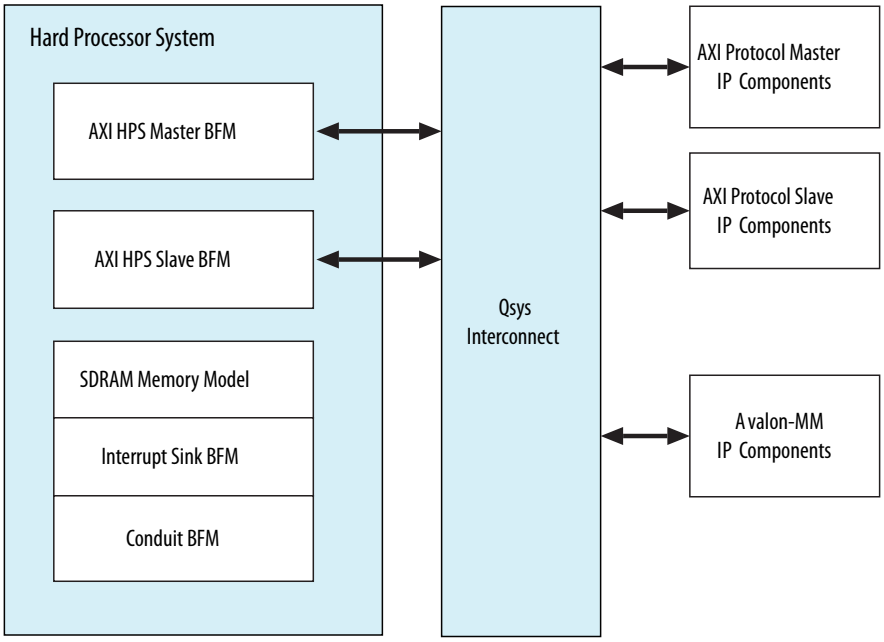
Figure 28-1: HPS BFM Block Diagram



The HPS BFMs use standard function calls from the Altera BFM application programming interface (API), as detailed in the remainder of this chapter.

HPS simulation supports only Verilog HDL or SystemVerilog simulation environments. Users with VHDL Custom IP can run BFM simulations so long as a mixed-language simulation license is available on their chosen simulator.

Simulation Flows

This section describes the simulation flows for an HPS-based design.

Altera provides functional register transfer level (RTL) simulation and post-fitter gate-level simulation flows. Both simulation flows involve the following major steps:

1. **Setting Up the HPS Component for Simulation** on page 28-3
2. **Generating the HPS Simulation Model in Qsys** on page 28-5
3. **Running the Simulation** on page 28-5

Related Information

Simulating Altera Designs
For general information about simulation, refer to the *Simulating Altera Designs* chapter in volume 3 of the *Quartus II Handbook*.

Setting Up the HPS Component for Simulation

The following steps outline how to set up the HPS component for simulation.

1. Add the HPS component from the Qsys Component Library.
2. Configure the component based on your application needs by selecting or deselecting the HPS-FPGA interfaces.
3. Connect the appropriate HPS interfaces to other components in the system. For example, connect the FPGA-to-HPS AXI slave interface to an AXI or Avalon-MM master interface in another component in the system.

When you create your component, make sure the conduit interfaces have the correct role names and widths and are opposite in direction to what is shown in the HPS Conduit Interfaces table.

HPS Conduit Interfaces Connecting to the FPGA on page 28-3

Related Information

Generating the HPS Simulation Model in Qsys

The following steps outline how to generate the simulation model.

1. In Qsys, click **Generate HDL** under the Generate menu.
2. For RTL simulation, perform the following steps:
   - Set **Create simulation model** to **Verilog**.
   - Click **Generate**.

     Note: VHDL is supported for HPS simulation and it requires a mix language simulator. However, the BFMs always need to be in verilog. Custom components can be in VHDL.

   For post-fit simulation, perform the following steps:

   - Turn on the **Create HDL design files for synthesis** option.
   - Turn on the **Create block symbol file (.bsf)**[64] option.

     Note: This is not a requirement for simulation or implementation unless schematic is used.
   - Click **Generate**.

Related Information

- **Instantiating the HPS Component** on page 26-1
- **Creating a System with Qsys**
  For more information about Qsys simulation, refer to "Simulating a Qsys System" in the *Creating a System with Qsys* chapter in volume 1 of the *Quartus II Handbook*.

Running the Simulation

The steps to run a simulation depend on whether you are running an RTL simulation or a post-fit simulation..

Running HPS RTL Simulation on page 28-5

Running HPS Post-Fit Simulation on page 28-6

Running HPS RTL Simulation

Qsys generates scripts for several simulators that you can use to complete the simulation process , as listed in the following table.

Table 28-10: Qsys-Generated Scripts for Supported Simulators

Simulator	Script Name	Directory
Mentor Graphics® Modelsim Altera Edition	**msim_ setup.tcl**	*<project directory>/<Qsys design name>*/**simulation/ mentor**
Cadence NC-Sim	**ncsim_ setup.sh**	*<project directory>/<Qsys design name>*/**simulation/ cadence**

[64] A **.bsf** file is only needed for schematic entry.

Simulator	Script Name	Directory
Synopsys VCS	**vcs_setup.sh**	*<project directory>*/*<Qsys design name>*/**simulation/synopsys/vcs**

Running HPS Post-Fit Simulation

To run HPS post-fit simulation after successful Qsys generation, perform the following steps:

1. Add the generated synthesis file set to your Quartus® II project by performing the following steps:
   a. In the Quartus II software, click **Settings** in the Assignments menu.
   b. In the **Settings** *<your Qsys system name>* dialog box, on the **Files** tab, browse to *<your project directory>*/*<your Qsys system name>***/synthesis/** and select *<your Qsys system name>***.qip**.
   c. Click **Open**. The **Select File** dialog box closes.
   d. Click **OK**. The **Settings** dialog box closes.
2. Optionally instantiate your HPS system as the top-level entity in your project.
3. Compile the design by clicking **Start Compilation** in the Processing menu.
4. Change the EDA Netlist Writer settings, if necessary, by performing the following steps:
   a. Click **Settings** in the Assignment menu.
   b. On the **Simulation** tab, under the **EDA Tool Settings** tab, you can specify the following EDA Netlist Writer settings:
      - **Tool name**—The name of the simulation tool
      - **Format for output netlist**
      - **Output directory**
   c. Click **OK**.
5. To create the post-fitter simulation model with Quartus II EDA Netlist Writer, perform the following steps:
   a. Click **Start** in the Processing menu.
   b. Click **Start EDA Netlist Writer**.

Post-Fit Simulation Files

Post-fit simulation is the simulation of the netlist generated from the original RTL design after it has been mapped, synthesized, and fit. The netlist represents the actual hardware and its connections as they

appear in the FPGA. Quartus generates the netlist and can generate a Standard Delay Format (**.sdf**) file with the timing information for all connections. The simulation can be functional only (without the timing information) where all wires and gates take zero time, or it can be a timing simulation where the time for all transitions is based on the SDF information.

Post-fit simulation can serve a number of different purposes. It can be used to perform a dynamic verification of the timing of the design, or it can be used to verify the functional correctness of either the design, the compilation flow (in particular, the fitter), or both.

BFM API Hierarchy Format

For post-fit simulation, you must call the BFM API in your test program with a specific hierarchy. The hierarchy format is:

```
<DUT>.\<HPS>|fpga_interfaces|<interface><space>.<BFM>.<API function>
```

Where:

- *<DUT>* is the instance name of the design under test that you instantiated in your test bench . The design under test is the HPS component.
- *<HPS>* is the HPS component instance name that you use in your Qsys system.
- *<interface>* is the instance name of a specific FPGA-to-HPS or HPS-to-FPGA interface. This name can be found in the **fpga_interfaces.sv** file located in *<project directory>*/*<Qsys design name>*/**synthesis/submodules**.
- *<space>*—You must insert one space character after the interface instance name.
- *<BFM>* is the BFM instance name. To identify the BFM instance name, in *<ACDS install>*/**ip/altera/hps/postfitter_simulation**, find the SystemVerilog file corresponding to the interface type that you are using. This SystemVerilog file contains the BFM instance name.

[65] The device simulation library is not needed with Modelsim-Altera.

For example, a path for the Lightweight HPS-to-FPGA master interface hierarchy could be formed as follows:

```
top.dut.\my_hps_component|fpga_interface|hps2fpga_light_weight .h2f_lw_axi_master
```

Notice the space after `hps2fpga_light_weight`. Omitting this space would cause simulation failure because the instance name `hps2fpga_light_weight` , including the space, is the name used in the post-fit simulation model generated by the Quartus II software.

Clock and Reset Interfaces

Clock Interface

Qsys generates the BFM clock for each clock input interface from the FPGA component. For the FPGA-to-HPS PLL reference clocks, specify the BFM reference clock frequency in the **Reference clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Qsys.

Table 28-12: HPS Clock Input Interface Simulation Model

The Altera clock source BFM application programming interface (API) applies to all the BFMs listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
`f2h_periph_ref_clock`	`f2h_periph_ref_clock_inst`
`f2h_sdram_ref_clock`	`f2h_sdram_ref_clock_inst`

Qsys generates the clock source BFM for each clock output interface from the HPS component. For HPS-to-FPGA user clocks, specify the BFM clock rate in the **User clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Qsys.

The HPS-to-FPGA TPIU generates a clock output to the FPGA, named `h2f_tpiu_clock`. In simulation, the clock source BFM also represents this clock output's behavior. Also, the HPS-to-FPGA debug APB interface generates a clock output to the FPGA, named `h2f_debug_apb_clock`.

Table 28-13: HPS Clock Output Interface Simulation Model

The Altera clock source BFM application programming interface (API) applies to all the BFMs listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
`h2f_user0_clock`	`h2f_user0_clock_inst`
`h2f_user1_clock`	`h2f_user1_clock_inst`
`h2f_user2_clock`	`h2f_user2_clock_inst`
`h2f_tpiu_clock`	`h2f_tpiu_clock_inst`

Reset Interface

The HPS reset request and handshake interfaces are connected to Altera conduit BFMs for simulation.

Table 28-14: HPS Reset Input Interface Simulation Model

You can monitor the reset request interface state changes or set the interface by using the API listed.

Interface Name	BFM Instance Name	API Function Names
f2h_cold_reset_req	f2h_cold_reset_req_inst	get_f2h_cold_rst_req_n()
f2h_debug_reset_req	f2h_debug_reset_req_inst	get_f2h_dbg_rst_req_n()
f2h_warm_reset_req	f2h_warm_reset_req_inst	get_f2h_warm_rst_req_n()
h2f_warm_reset_handshake	h2f_warm_reset_handshake_inst	set_h2f_pending_rst_req_n() get_f2h_pending_rst_ack_n()

Table 28-15: HPS Reset Output Interface Simulation Model

The Altera reset source BFM application programming interface applies to all the BFMs listed.

Interface Name	BFM Instance Name
h2f_reset	h2f_reset_inst
h2f_cold_reset	h2f_cold_reset_inst
h2f_debug_apb_reset	h2f_debug_apb_reset_inst

Table 28-16: Configuration of Reset Source BFM for HPS Reset Output Interface

The HPS reset output interface is connected to a reset source BFM. Qsys configures the BFM as shown in the following table. The parameter value of the instantiated BFM is configured for HPS simulation.

Parameter	BFM Value	Meaning
Assert reset high	Off	This parameter is off, specifying an active-low reset signal from the BFM.
Cycles of initial reset	0	This parameter is 0, specifying that the BFM does not assert the reset signal automatically.

  The Mentor Verification IP User guide provides details of the API and connection guidelines for the AXI3 and AXI4 BFMs.

FPGA-to-HPS SDRAM Interface

The HPS component contains a memory interface simulation model to which all of the FPGA-to-HPS SDRAM interfaces are connected. The model is based on the HPS implementation and provides cycle-level accuracy, reflecting the true bandwidth and latency of the interface. However, the model does not have the detailed configuration provided by the HPS software, and hence does not reflect any inter-port scheduling that might occur under contention on the real hardware when different priorities or weights are used.

Related Information

Functional Description—Hard Memory Interface
For more information, refer to "EMI-Related HPS Features in SoC Devices" in the *Functional Description—Hard Memory Interface* chapter in volume 3 of the *External Memory Interface Handbook*.

HPS Memory Interface Simulation

The HPS component provides a complete simulation model of the HPS memory interface controller and PHY, with cycle-level accuracy, comparable to the simulation models for the FPGA memory interface.

There are three simulation modes:

- Skip-cal - In the simulation, the memory comes up already calibrated.
- Quick-cal - The calibration process is sped up so that you do not have to wait so long into the simulation to start reading or writing memory.
- Full-cal - The entire calibration sequence is simulated. This means that you will be waiting a while before the memory controller is online.

The simulation model supports only the skip-cal simulation mode. Quick-cal and full-cal are not supported. Although an example design is not provided, you can create a test design by adding the traffic generator component to your design using Qsys. Also, the HPS simulation model does not use external memory pins to connect to the DDR memory model; instead, the memory model is incorporated directly into the HPS SDRAM interface simulation modules.

One of the various ways you can simulate the FPGA-to-SDRAM interfaces is by:

- Bring the interfaces out of reset; otherwise, transactions cannot occur.
- Connect the H2F reset to the F2H port resets.
- Add a stage to your testbench to assert and deassert the H2F reset in the HPS.

The appropriate Verilog code is shown below:

```
Initial
begin
   // Assert reset
<base name>.hps.fpga_interfaces.h2f_reset_inst.reset_assert();
   // Delay
   #1
   // Deassert reset
<base name>.hps.fpga_interfaces.h2f_reset_inst.reset_deassert();
end
```

HPS-to-FPGA MPU Event Interface

The HPS-to-FPGA MPU event interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 28-20: HPS-to-FPGA MPU Event Interface Simulation Model

The usage of conduit `get_*()` and `set_*()` API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
h2f_mpu_events	h2f_mpu_events_inst	get_h2f_mpu_eventi() set_h2f_mpu_evento() set_h2f_mpu_standbywfe() set_h2f_mpu_standbywfi()	get_eventi() set_evento() set_standbywfe() set_standbywfi()

av_5v4 Subscribe Send Feedback

The Altera system-on-a-chip (SoC) device provides a variety of ways to boot the hard processor system (HPS) and configure the FPGA portion.

Boot Overview

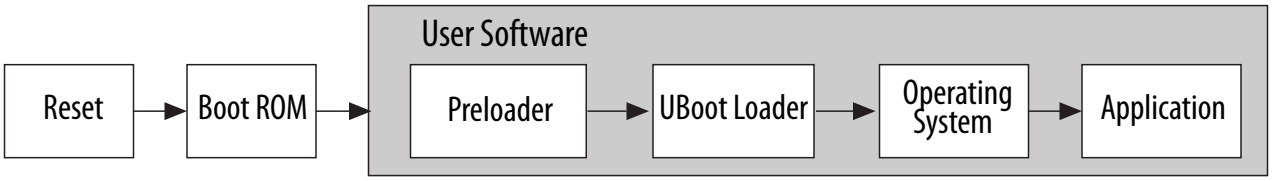
The boot flow of the HPS is a multi-stage process. Each stage is responsible for loading the next stage.

The first software stage is the boot ROM. The boot ROM code locates and executes the second software stage, called the preloader. The preloader locates, and if present, executes the next software stage. The preloader and subsequent software stages (if present) are collectively referred to as user software.

Only the boot ROM code is located in the HPS. Subsequent software is located external to the HPS and is provided by users. The boot ROM code is only aware of the preloader and not aware of any potential subsequent software stages.

The figure below illustrates the typical boot flow. However, there may be more or less software stages in the user software than shown and the roles of the software stages may vary.

Figure A-1: Typical Boot Flow



FPGA Configuration Overview

After power is applied to the FPGA portion of the SoC, configuration may begin. The FPGA may be configured through a variety of ways, such as through the HPS, JTAG, or an external host.

The control block (CB) in the FPGA portion of the device is responsible for obtaining an FPGA configuration image and configuring the FPGA. The FPGA configuration ends when the configuration image has been fully loaded and the FPGA enters user mode. The FPGA configuration image is provided by users and is typically stored in external non-volatile flash-based memory. The FPGA CB can obtain a configura-

Booting and Configuration Options

SoC initialization includes the booting of the HPS and the configuration of the FPGA fabric and I/O.

Depending on the initialization option you choose, the I/O configuration is handled differently. You can choose one of the three initialization options:

- The HPS boot and FPGA configuration occur separately.
- The HPS boots first and then configures the FPGA.
- The HPS boots from the FPGA after the FPGA is configured.

The following three figures illustrate the possible HPS boot and FPGA configuration schemes. The arrows in the figures denote the data flow direction.

Figure A-2: Separate FPGA Configuration and HPS Booting

In the figure below, the FPGA configuration and HPS boot can occur independently. The FPGA obtains its configuration image from a non-HPS source, while the HPS boot ROM obtains its preloader from a non-FPGA fabric source.

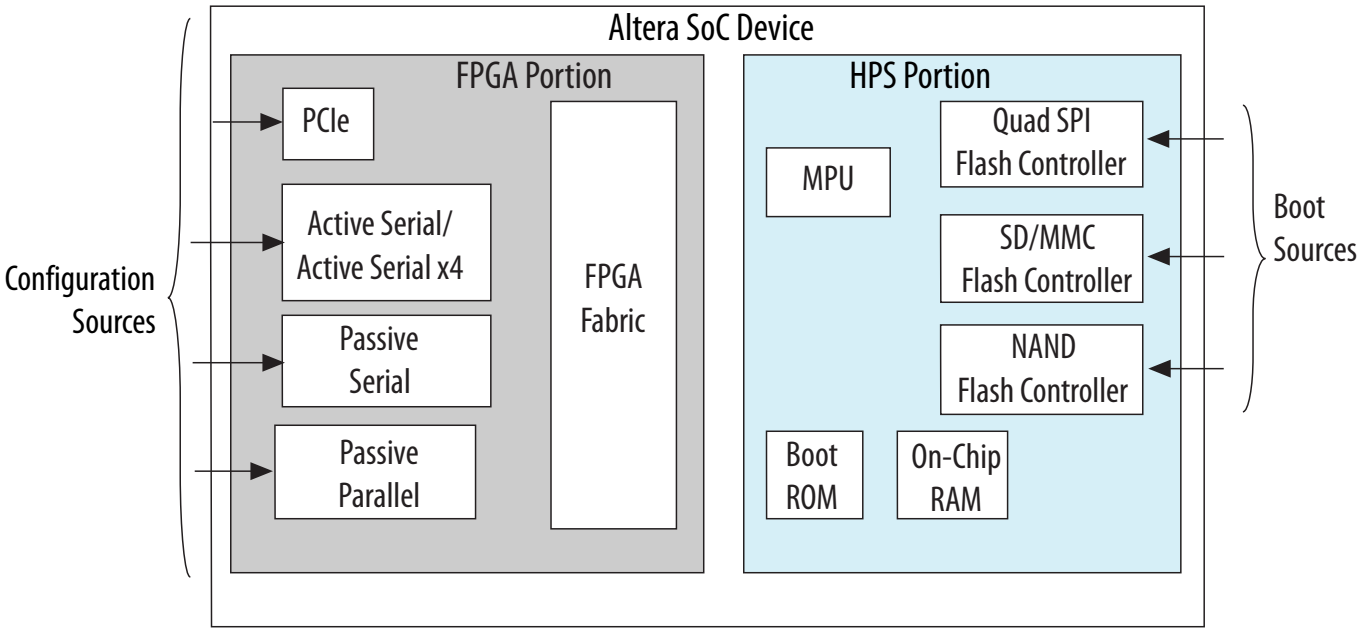

Figure A-3: HPS Boots First and then Configures the FPGA

In the figure below, the HPS boots first through one of its non-FPGA fabric boot sources. The FPGA does not need to be configured in order for the HPS to boot. However, the FPGA must be in a power-on state for the HPS to reset properly. The software on the HPS obtains the FPGA configuration image from any of its flash memory devices or communication interfaces, for example, the Ethernet media access controller (EMAC).

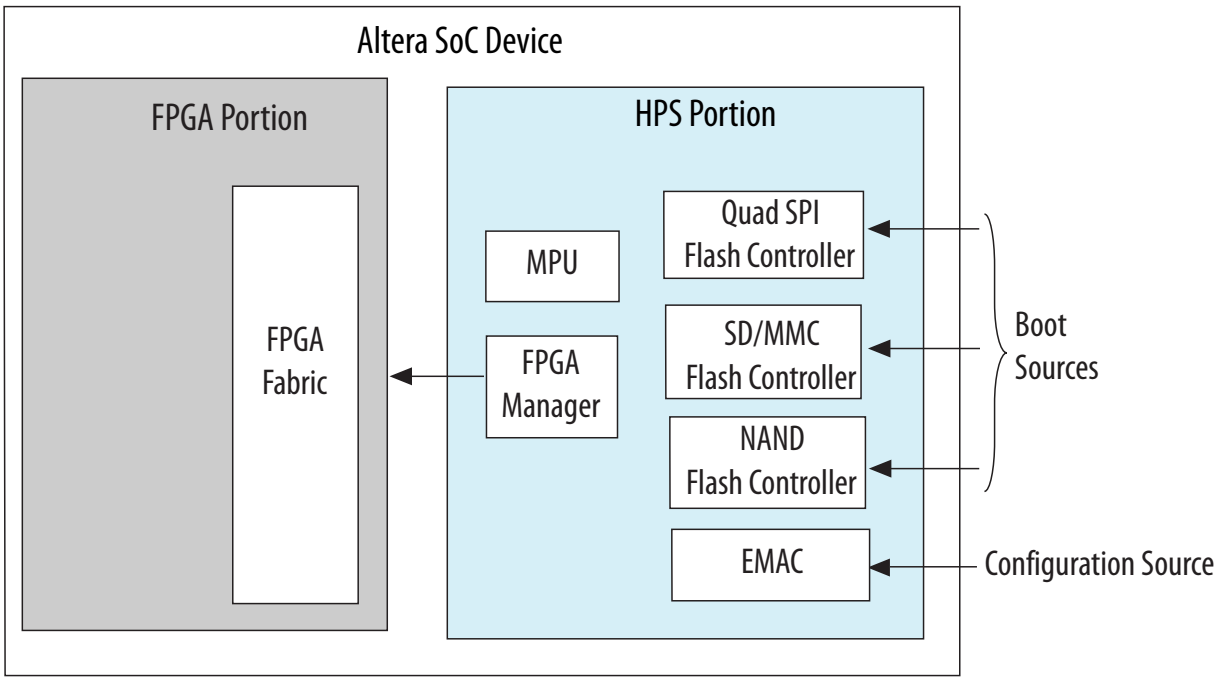

Figure A-4: HPS Boots From FPGA

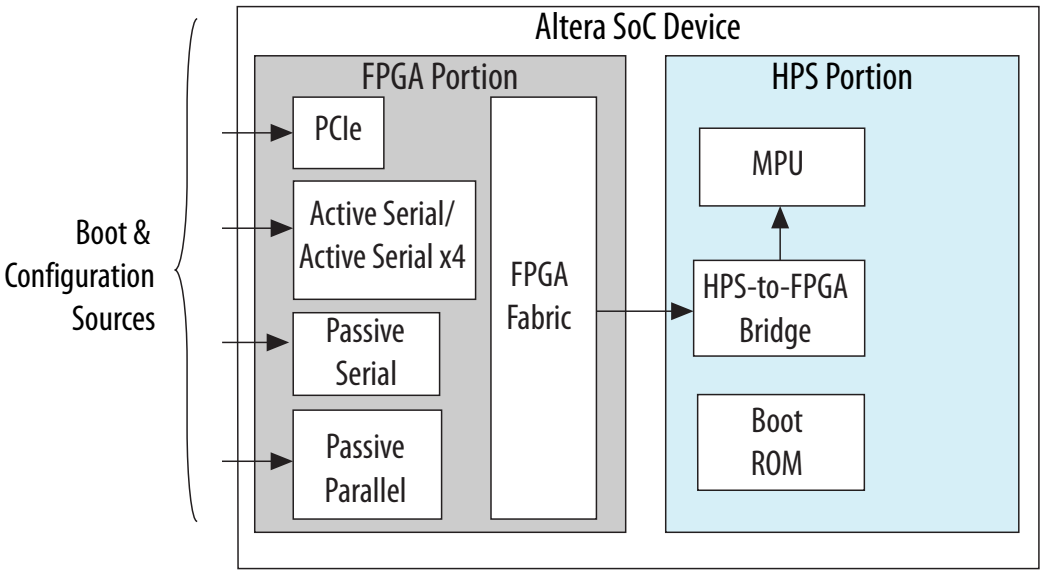
In the figure below, the FPGA is configured first through one of its non-HPS configuration sources and then the HPS executes the preloader from the FPGA. In this situation, the HPS should not be released from reset until the FPGA is powered on and programmed. Once the FPGA is in user mode and the HPS has been released from reset, the boot ROM code begins executing. The HPS boot ROM code executes the preloader from the FPGA fabric over the HPS-to-FPGA bridge.



Boot Definitions

The following sections contain basic terms and definitions that are part of the boot process.

Reset

Reset precedes the boot stages and is an important part of device initialization. There are two different reset types: cold reset and warm reset.

The boot process begins when CPU0 in the MPU exits from the reset state. When CPU0 exits from reset, it starts executing code at the reset exception address where the boot ROM code is located. CPU1 remains in reset during this time and is brought out of reset by user software.

With warm reset, some software registers are preserved and the boot process may skip some steps depending on software settings. In addition, on a warm reset, the preloader has the ability to be executed from on-chip RAM.

Boot ROM

The boot ROM code is 64 KB in size and located in on-chip ROM at address range 0xFFFD0000 to 0xFFFDFFFF. The function of the boot ROM code is to determine the boot source, initialize the HPS after a reset, and jump to the preloader. In the case of indirect execution, the boot ROM code loads the

preloader image from the flash memory to on-chip RAM. The boot ROM performs the following actions to initialize the HPS:

- Enable instruction cache, branch predictor, floating point unit, NEON vector unit of CPU0
- Sets up the level 4 (L4) watchdog 0 timer
- Configures the main PLL and peripheral PLL based on the CSEL value
- Initializes the flash controller to default settings

When booting from flash memory, the boot ROM code uses the top 4 KB of the on-chip RAM as data workspace. This area is reserved for the boot ROM code after a reset until the boot ROM code passes software control to preloader. For a warm RAM boot or a cold boot from FPGA, the boot ROM code does not reserve the top 4 KB of the on-chip RAM, and the user may place user data in this area without being overwritten by boot ROM.

The boot process begins when CPU0 exits from the reset state. The boot ROM code only executes on CPU0. CPU1 is held in reset while boot ROM executes on CPU0. When a CPU0 exits from reset, it starts executing code at the reset exception address.

When CPU0 exits the boot ROM code and starts executing user software, the boot ROM access is disabled. The user software in CPU0 must map the user software exception vectors at 0x0 (which is previously mapped to boot ROM exception vectors). The user software also has the option of releasing CPU1 from reset. If CPU1 is released from reset, CPU1 executes the user software exception instead of boot ROM.

Boot Select

The boot select (BSEL) pins offer multiple methods to obtain the preloader image. On a cold reset or when a RAM boot has not been requested, the user asserts the BSEL pins on the device to indicate the boot source that is required. These pins are sampled on deassertion of cold reset and are written to the `bootinfo` register in the System Manager. The value of this register is read during boot ROM execution so that the appropriate interface pins can be initialized. If the boot source is from FPGA, the `bsel` field value reads as 0x1 in the `bootinfo` register and no HPS interface is configured for external boot.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Table A-1: BSEL Values for Boot Source Selection

BSEL[2:0] Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.3 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.3 V SD/MMC flash memory with internal transceiver

BSEL[2:0] Value	Flash Device
0x6	1.8 V quad SPI flash memory
0x7	3.3 V quad SPI flash memory

Note: If the BSEL value is set to 0x4 or 0x5, an external translation transceiver may be required to supply level-shifting and isolation if the SD cards interfacing to the SD/MMC controller must operate at a different voltage than the controller interface. Please refer to the *SD/MMC Controller* chapter for more information.

The HPS flash sources can store various file types, such as:

- FPGA programming files
- Preloader binary file (up to four copies)
- Boot loader binary file
- Operating system binary files
- Application file system

When BSEL = 0x1, the boot source is the FPGA and the CSEL pins are ignored. PLLs are bypassed so that OSC1 drives all the clocks.

If an HPS flash interface has been selected to load the boot image, then the boot ROM enables and configures that interface before loading the boot image into on-chip RAM, verifying it and passing software control to the preloader.

If the external RAM boot source is invalid or if the boot ROM code cannot find a valid image in flash, then the boot ROM code checks to see if there is a fallback image in the FPGA. If there is then the boot ROM executes that.

If the FPGA fabric is the boot source, the boot ROM code waits until the FPGA portion of the device is in user mode, and is ready to execute code and then passes software control to the preloader in the FPGA RAM.

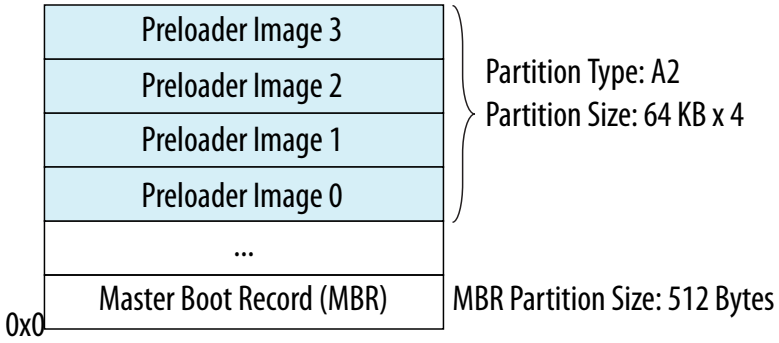
Flash Memory Devices for Booting

The memory controllers and devices that contain the boot loader image have configuration requirements for proper boot from flash.

SD/MMC Flash Devices

The following figure shows an SD/MMC flash image layout example for boot. The master boot record (MBR) is located in the first 512 bytes of the memory. The MBR contains information about the partitions (address and size of partition). The preloader image is stored in partition A2. Partition A2 is a custom raw partition with no file system.

Figure A-5: SD/MMC Flash Image Layout



The SD/MMC controller supports two booting modes:

- MBR (partition) mode
  - The boot image is read from a custom partition (0xA2)
  - The first image is located at the beginning of the partition, at offset 0x0
  - Start address = partition start address
- Raw mode
  - If the MBR signature is not found, SD/MMC driver assumes it is in raw mode
  - The boot image data is read directly from sectors in the user area and is located at the first sector of the SD/MMC
  - The first image is located at the start of the memory card, at offset 0x0
  - Start address = 0x0

The MBR contains the partition table, which is always located in the first sector (LBA0) with a memory size of 512 bytes. The MBR consists of executable code, four partition entries, and the MBR signature. A MBR can be created by specific tools like the FDISK program.

Table A-9: MBR Structure

Offset	Size (In Bytes)	Description
0x000	446	Code area
0x1BE	16	Partition entry for partition 1
0x1CE	16	Partition entry for partition 2
0x1DE	16	Partition entry for partition 3
0x1EE	16	Partition entry for partition 4
0x1FE	2	MBR signature: 0xAA55

The standard MBR structure contains a partition with four 16-byte entries. Thus, memory cards using this standard table cannot have more than four primary partitions or up to three primary partitions and one extended partition.

Each partition type is defined by the partition entry. The boot images are stored in a primary partition with custom partition type (0xA2). The SD/MMC flash driver does not support a file system, so the boot images are located in partition A2 at fixed locations.

Table A-10: Partition Entry

Offset	Size (In Bytes)	Description
0x0	1	Boot indicator. 0x80 indicates that it is bootable.
0x1	3	Starting CHS value
0x4	1	Partition type
0x5	3	Ending CHS value
0x8	4	LBA of first section in partition
0xB	4	Number of sectors in partition

The boot ROM code configures the SD/MMC controller to default settings for the supported SD/MMC flash memory.

Default Settings of the SD/MMC Controller

Table A-11: SD/MMC Controller Default Settings

Parameter	Default	Register Value
Card type	1 bit	The card type register (`ctype`) in the SD/MMC controller registers (`sdmmc`) = 0x0
Timeout	Maximum	The timeout register (`tmout`) = 0xFFFFFFFF

Parameter		Default	Register Value
FIFO threshold RX watermark level		1	The RX watermark level field (`rx_wmark`) of the FIFO threshold watermark register (`fifoth`) = 0x1
Clock source		0	The clock source register (`clksrc`) = 0x0
Block size		512	The block size register (`blksiz`) = 0x200
Clock divider	Identification mode	32	The clock divider register (`clkdiv`)= 0x10 (2*16=32)
	Data transfer mode	Bypass	The clock divider register (`clkdiv`)= 0x00

Parameter	Default	Register Value
External Device Power enable	Disabled (Power Off)	The power_enable bit in the pwren register is programmed to 0x0 out of reset, meaning the sdmmc_pwren signal is not active and does not do anything at boot time. A pull-up should be attached to the sdmmc_pwren pin for proper functionality. **Note:** If the SD/MMC controller is used as the boot source, then power to the corresponding SD card must be supplied from a power controller on the board. After boot has completed and the SD/MMC controller has been fully configured, the sdmmc_pwren signal can be used to turn on and off the SD card through the pwren register.

CSEL Settings for the SD/MMC Controller

Table A-12: SD/MMC Controller CSEL Pin Settings

Setting	CSEL Pin			
	0	1	2	3
osc1_clk (EOSC1 pin) range	10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz

Setting		CSEL Pin			
		0	1	2	3
ID mode	Device clock (sdmmc_cclk_out)	osc1_clk/128, 391 KHz max	osc1_clk/32, 391 KHz max	osc1_clk/64, 391 KHz max	osc1_clk/128, 391 KHz max
	Controller baud rate divisor	32	32	32	32
Data transfer mode	Device clock (sdmmc_cclk_out)	osc1_clk/4, 12.5 MHz max	osc1_clk*1, 12.5 MHz max	osc1_clk/2, 12.5 MHz max	osc1_clk/4, 12.5 MHz max
	Controller baud rate divisor (even numbers only)	1 (bypass)	1 (bypass)	1 (bypass)	1 (bypass)
Controller clock (sdmmc_clk)		osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk, 50 MHz max
mpu_clk		osc1_clk, 50 MHz max	osc1_clk*32, 400 MHz max	osc1_clk*16, 400 MHz max	osc1_clk*8, 400 MHz max
PLL modes		Bypassed	Locked	Locked	Locked

NAND Flash Devices

The NAND subsystem reserves at least the first 256 KB on the NAND device. If the NAND flash device has blocks greater than 64 KB, then the NAND subsystem reserves the first four blocks on the device. For a NAND device with less than 64 KB block size, the preloader image must be placed in multiple blocks. The NAND subsystem expects to find up to four preloader images on the NAND device. You may have less than four if required. The preloader image should always be at the start of a physical page. Because a block is the smallest area used for erase operation, any update to a particular image does not affect other images.

Figure A-6: NAND Flash Image Layout for 64 KB Memory Blocks

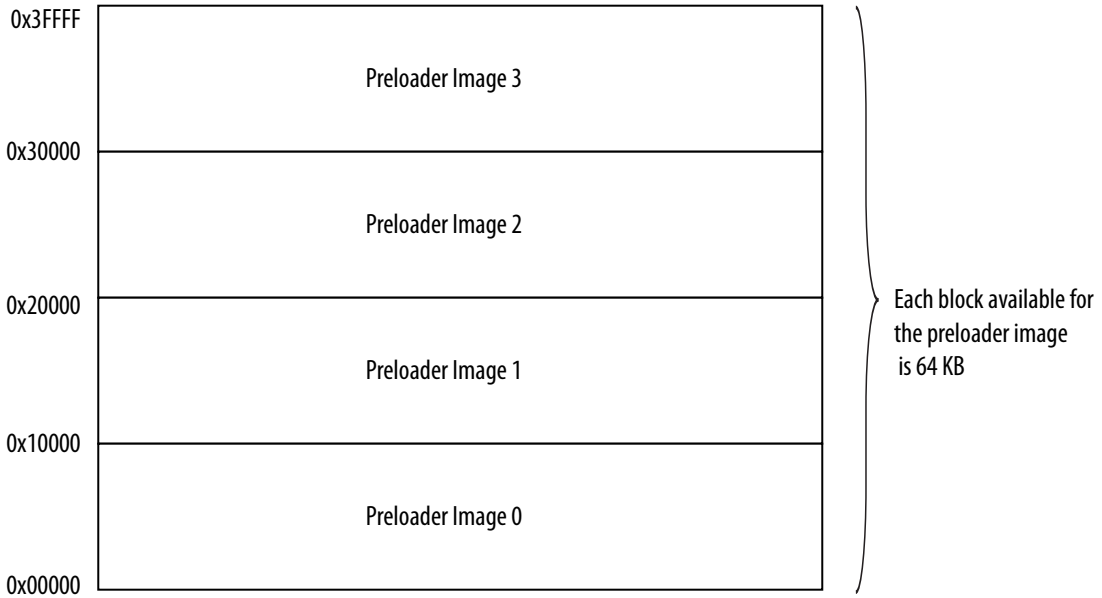

Figure A-7: NAND Flash Image Layout for 128 KB Memory Blocks

NAND Flash Driver Features Supported in the Boot ROM Code

Table A-13: NAND Flash Support Features

Feature	Driver Support
Device	Open NAND Flash Interface (ONFI) 1.0 raw NAND or electronic signature devices, single layer cell (SLC)
Chip select	CS0 only. Only CS0 is available to the HPS, the other three chip selects are routed out to the FPGA portion of the device
Bus width	8-bit only
Page size	512 bytes, 2 KB, 4 KB, or 8 KB
Page per block	32, 64, 128, 384 and 512
ECC	512-bytes with 8-bit correction

CSEL Settings for the NAND Controller

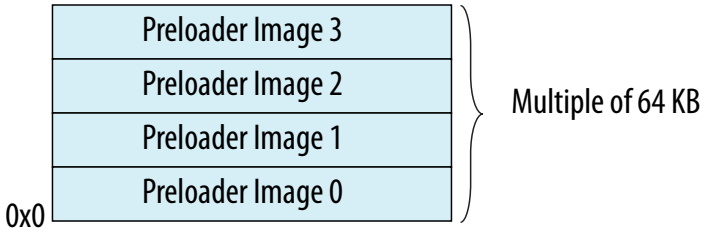
Table A-14: NAND Controller CSEL Pin Settings

Setting	CSEL Pin			
	0	1	2	3
`osc1_clk` (`EOSC1` pin) range	10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz
Device frequency (`nand_x_clk`/4)	`osc1_clk`/4, 12.5 MHz max	`osc1_clk`*8/4, 25 MHz max	`osc1_clk`*4/4, 25 MHz max	`osc1_clk`2/4, 25 MHz max
Controller clock (`nand_x_clk`)	`osc1_clk`, 50 MHz max	`osc1_clk`*8, 100 MHz max	`osc1_clk`*4, 100 MHz max	`osc1_clk`*2, 100 MHz max
`mpu_clk`	`osc1_clk`, 50 MHz max	`osc1_clk`*32, 400 MHz max	`osc1_clk`*16, 400 MHz max	`osc1_clk`*8, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

Quad SPI Flash Devices

The figure below shows the quad SPI flash image layout. The preloader image is always located at offsets that are multiples of 64 KB.

Figure A-9: Quad SPI Flash Image Layout



The boot ROM code configures the quad SPI controller to default settings for the supported SPI or quad SPI flash memory.

Related Information

Quad SPI Controller Default Settings

Table A-15: Quad SPI Controller Default Settings

Parameter	Default Setting	Register Value
SPI baud rate	Divide by 4	The master mode baud rate divisor field (`bauddiv`) of the quad SPI configuration register (`cfg`) in the quad SPI controller registers (`qspiregs`) = 1.
Read opcode	CSEL = 0 or 1: Normal read CSEL = 2 or 3: Fast read	The read opcode in non-XIP mode field (`rdopcode`) in the device read instruction register (`devrd`) = 0x3 (for normal read) and 0xB (for fast read).
Instruction type	Single I/O (1 bit wide)	The address transfer width field (`addrwidth`) and data transfer width field (`datawidth`) of the `devrd` register = 0.
Number of address bytes	3 bytes	The number of address bytes field (`numaddrbytes`) of the device size register (`devsz`) = 2. **Note:** Before a reset, you must ensure that the QSPI flash device is configured to 3 byte address mode for the boot ROM to function properly.

Parameter	Default Setting	Register Value
Delay in terms of qspi_clkclock cycles for the length that the master mode chip select outputs are deasserted between words when the clock phase is zero	The default setting in clock cycles must equal 200 ns	The clock delay for chip select deassert (field nss in the quad SPI device delay register (delay)). Refer to delay[31:24] in the "Quad SPI Flash Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Delay in terms of qspi_clk clock cycles between one chip select being deactivated and the activation of another. This delay ensures a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty	The default setting is 0 clock cycles.	The clock delay for chip select deactivation (field btwn in the delay register = 0x0).
Delay in terms of qspi_clk clock cycles between the last bit of the current transaction and the first bit of the next transaction. If the clock phase is zero, the first bit of the next transaction refers to the cycle in which the chip select is deselected	The default setting in clock cycles must equal 20 ns.	The clock delay for last transaction bit (field after in the delay register). Refer to delay[15:8] in the "Quad SPI Flash Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Added delay in terms of qspi_clk clock cycles between setting qspi_n_ss_out low and first bit transfer	The default setting in clock cycles must equal 20 ns.	The clock delay of qspi_n_ss_out (field init in the delay register). Refer to delay[7:0] in the "Quad SPI Flash Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.

Quad SPI Flash Delay Configuration

The delay register in the quad SPI controller configures relative delay of the generation of the master output signals. All timings are defined in cycles of qspi_clk.

The quad SPI flash memory must meet the following timing requirements:

- T_{SLCH}: 20 ns
  - T_{SLCH} is used to calculate the `init` field (`delay[7:0]`) in the `delay` register. The `init` field represents the delay in `qspi_clk` clocks between pulling the device chip select (`qspi_n_ss_out`) low and the first bit transfer.
- T_{CHSH}: 20 ns
  - T_{CHSH} is used to calculate the `after` field (`delay[15:8]`) in the `delay` register. The `after` field represents the delay in the `qspi_clk` clocks between last bit of the current transaction and the deassertion of the device chip select (`qspi_n_ss_out`).
- T_{SHSL}: 200 ns
  - T_{SHSL} is used to calculate the `nss` field (`delay[31:24]`) in the `delay` register and is the delay in the `qspi_clk` clocks for the length that the master mode chip select outputs are deasserted between transactions.
- T_{qspi_clk} is the master reference clock/external clock, `qspi_clk`.

The formulas to calculate the fields in the `delay` register are:

`delay[7:0]`= `init` = T_{SLCH}/T_{qspi_clk}

`delay[15:8]`= `after` = T_{CHSH}/T_{qspi_clk}

`delay[31:24]`= `nss` = $(T_{SHSL} - T_{sclk_out})/T_{qspi_clk}$

Table A-16: Quad SPI Flash Delay Configuration

CSEL Pin	T_{qspi_clk} (ns)	T_{sclk_out} (ns)	Device Delay Register		
			delay[7:0] (init)	delay[15:8] (after)	delay[31:24] (nss)
0	20	80	1	1	6
1	10	40	2	2	16
2–3	5	20	4	4	36

Quad SPI Controller CSEL Settings

Table A-17: Quad SPI Controller CSEL Pin Settings

Setting	CSEL Pin			
	0[66]	1	2	3
`osc1_clk` (`EOSC1` pin) range	10–50 MHz	20–50 MHz	25–50 MHz	10–25 MHz
Device clock (`sclk_out`)	`osc1_clk`/4, 12.5 MHz max	`osc1_clk`/2, 25 MHz max	`osc1_clk`*1, 50 MHz max	`osc1_clk`*2, 50 MHz max
Controller clock (`qspi_clk`)	`osc1_clk`, 50 MHz max	`osc1_clk`*2, 100 MHz max	`osc1_clk`*4, 200 MHz max	`osc1_clk`*8, 200 MHz max

[66] Not applicable when on WARM reset.

Setting	CSEL Pin			
	0[66]	1	2	3
Controller baud rate divisor (even numbers only)	4	4	4	4
Flash read instruction (1 dummy byte for READ_FAST)	READ	READ	READ_FAST	READ_FAST
`mpu_clk`	`osc1_clk`, 50 MHz max	`osc1_clk*8`, 400 MHz max	`osc1_clk*8`, 400 MHz max	`osc1_clk*16`, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

Clock Select

The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

The clock select (CSEL) pins are asserted to select the speed of the HPS boot interface. If the FPGA is used as the boot source, the CSEL pins are ignored. The CSEL values define the main PLL, `l2_mp_clk` and `l4_sp_clk`. Based on the clock source and clock select settings, boot ROM configures the main PLL and peripheral PLL parameters and the clock dividers for clocks derived from the PLLs.

Note: The terms CSEL and CLKSEL are used interchangeably in Altera documentation to refer to clock select.

Note: At power-up or reset, when `CSEL[3:0]`=0x0 or `BSEL[2:0]` is configured to boot from FPGA, the HPS PLLs are in bypass mode. Thus, HPS user clocks exported to the FPGA fabric run at `osc1_clk` frequency.

I/O Configuration

The flash devices needed for booting must be connected to specific I/Os. The Boot ROM configures these I/Os depending on the flash device selected by boot select setting. To configure the I/Os, the boot ROM performs pin muxing and pin configuration on these I/Os.

On cold reset, the boot ROM always configures the pin muxes and pin configurations. On warm reset, the user has the capability to specify whether or not the boot ROM code configures the I/Os and pin muxes for boot pins after a warm reset. This configuration on warm reset is enabled by programming the `ctrl` register in the Boot ROM Code Register group of the System Manager.

Related Information

Hard Processor System I/O Pin Multiplexing

Refer to the *Hard Processor Subsystem I/O Multiplexing* chapter for more information regarding booting I/O options and configuration.

[66] Not applicable when on WARM reset.

L4 Watchdog 0 Timer

The boot ROM enables the L4 Watchdog 0 Timer early in the boot process.

This watchdog is reserved for the boot ROM until the preloader indicates that it has started correctly and taken control of the exception vectors. The timeout is at least one second, depending on the clock select setting. Because the watchdog is reset just before the control passes to preloader, the preloader must reset the watchdog when it begins execution.

The L4 watchdog 0 timer is reserved for boot ROM use. While booting, if a watchdog reset happens before software control passes to the preloader, the boot ROM code attempts to load the last valid preloader image, identified by the `initswlastld` register in the System Manager.

If the watchdog reset happens after the preloader has started executing but before it writes a valid value to `initswstate` register, the boot ROM increments `initswlastld` and attempts to load that image. If the watchdog reset happens after the preloader writes a valid value to `initswstate` register, the boot ROM code attempts to load the image indicated by `initswlastld` register.

Preloader

The function of the preloader is user-defined. However, typical functions include:

- Initializing the SDRAM interface
- Configuring the HPS I/O pins
- Initializing the interface that loads the next stage of software

Initializing the SDRAM allows the preloader to load the next stage of the boot software (that might not fit in the 60 KB available in the on-chip RAM) into SDRAM. A typical next software stage is the open source boot loader, U-boot. The preloader is allowed to load the next boot software stage from any device available to the HPS. Typical sources include the same flash device that contains the preloader, a different flash device, or a communication interface such as an EMAC.

U-Boot Loader

The optional U-boot loader loads the operating system and passes software control to the operating system.

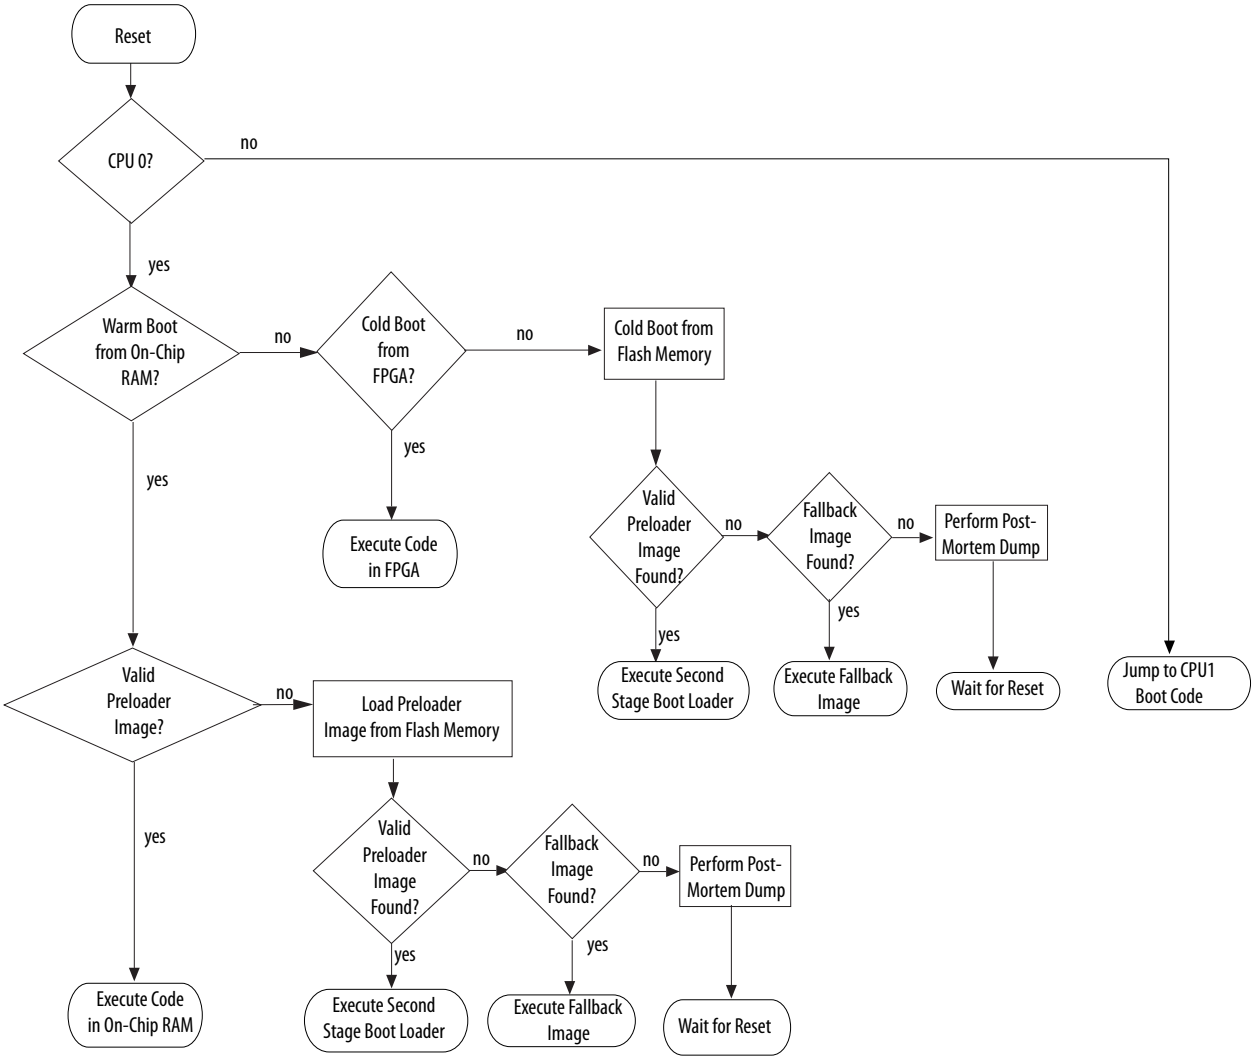
Boot ROM Flow

On a cold reset, the HPS boot process starts when CPU0 is released from reset (for example, on a power up) and executes code in the internal boot ROM at the reset exception address. The boot ROM code brings the SoC out of reset and into a known state. After boot ROM code is exited, control passes to the next stage of the boot software, referred to as the preloader. The preloader can be customized and is typically stored external to the HPS in a nonvolatile flash-based memory or in on-chip RAM within the FPGA. Beyond that, another boot layer can be executed before loading the operating system software.

This section describes the software flow from reset until the boot ROM code passes software control to the preloader.

The following figure illustrates that the boot ROM code can perform a warm boot from on-chip RAM, a cold boot from the FPGA portion of the device, or a cold boot from flash memory.

Figure A-10: BOOT ROM FLOW



After a reset, the boot ROM code determines which CPU it is executing on. If it is executing on CPU 1, then control is passed to CPU1 and the boot ROM execution is complete. This event only happens if the user code releases CPU1 without resetting the exception vectors.

If the boot ROM is executing on CPU0, it checks to see if an on-chip RAM boot is requested. An on-chip RAM boot can only occur on a warm reset. Warm boot from on-chip RAM has the highest priority to execute if the `warmramgrp` registers in the `romcodegrp` group in the system manager has been configured to support booting from on-chip RAM on a warm reset. If the `enable` register in the System Manager is set to 0xAE9EFEBC, then the boot ROM code will attempt to boot from on-chip RAM on a warm reset and the boot ROM will not configure boot I/Os, pin-muxes or clocks. The `datastart` and `length` registers in System Manager allow you to program the offset of the beginning of code and the length of the region of on-chip RAM for CRC validation. If the `length` register is clear, then boot ROM will not perform a CRC calculation on the on-chip RAM.

If a valid preloader image cannot be found in the on-chip RAM, or the preloader in the on-chip RAM fails the CRC check, the boot ROM code attempts to load the last valid preloader image loaded from the flash

memory, identified by the `index` field of the initial software last image loaded register (`initswlastld`) in the `romcodegrp` group in the system manager. If the image is invalid, boot ROM code attempts to load up to three subsequent images from flash memory. If a valid preloader image cannot be found in the on-chip RAM or flash memory, the boot ROM code checks the FPGA portion of the device for a fallback image.

If the warm RAM boot has failed or if a cold reset has occurred, then the boot ROM reads the BSEL value in the `bootinfo` register of the System Manager. If the FPGA is selected as the boot source, then the boot ROM code attempts to execute code at address 0xC0000000 across the HPS-to-FPGA bridge (offset 0x00000000 from bridge). No error conditions are generated if the FPGA does not initialize properly and the watchdog is not enabled for time-out. Instead, the boot ROM continues to wait until the FPGA is available.

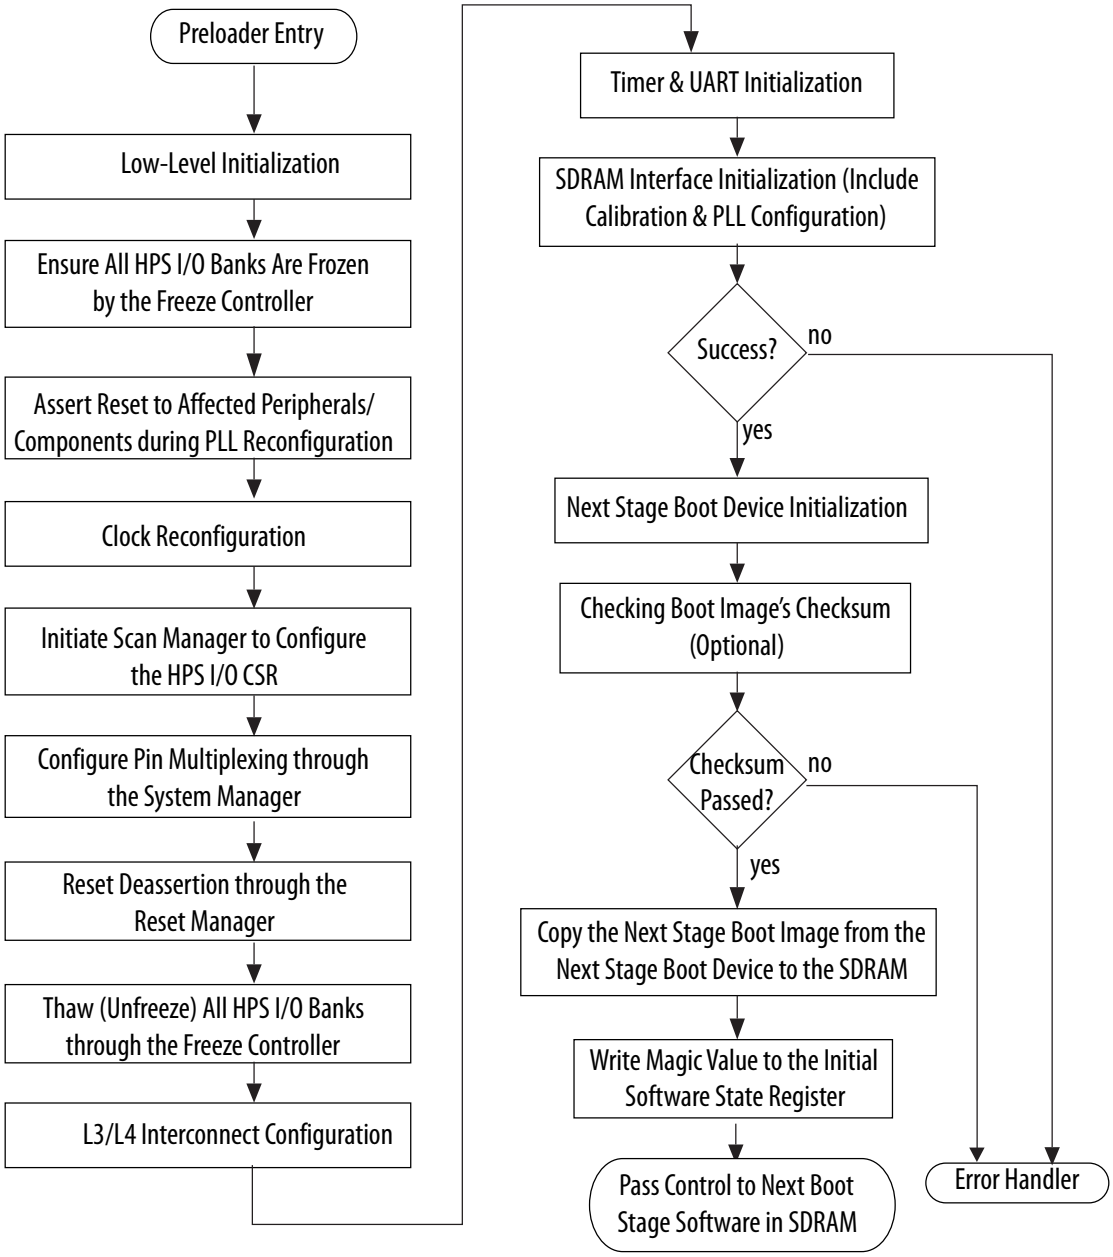
If the BSEL bits indicate a boot from external flash, then the boot ROM code attempts to load an image from a flash device into the on-chip RAM, verify and execute it. If the BSEL is invalid or the boot ROM code cannot find a valid image in the flash, then the boot ROM code checks if there is a fallback image in the FPGA. If there is, then the boot ROM executes the fallback image. If there is no fallback image then the boot ROM performs a post-mortem dump of information into the on-chip RAM and awaits a reset.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Typical Preloader Boot Flow

This section describes a typical software flow from the preloader entry point until the software passes control to the next stage boot software.

Figure A-11: Typical Preoader Flow



Low-level initialization steps include reconfiguring or disabling the L4 watchdog 0 timer, invalidating the instruction cache and branch predictor, remapping the on-chip RAM to the lowest memory region, and setting up the data area.

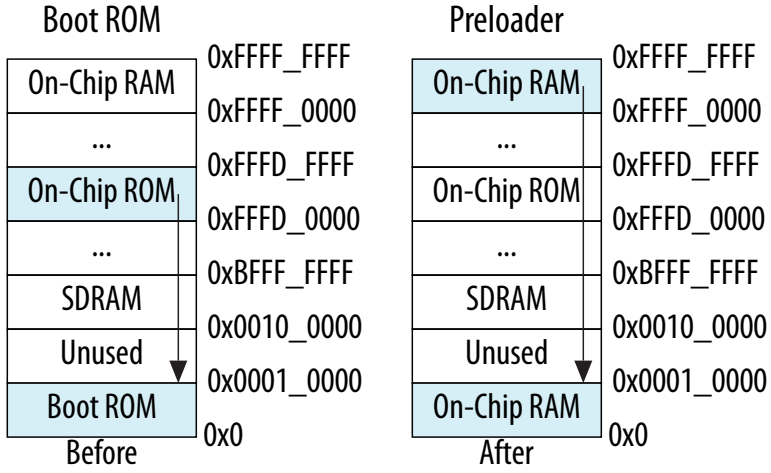
Upon entering the preloader, the L4 watchdog 0 timer is active. The preloader can disable, reconfigure, or leave the watchdog timer unchanged. Once enabled after reset, the watchdog timer cannot be disabled, only paused.

The instruction cache and branch predictor, which were previously enabled by the boot ROM code, need to be invalidated.

The preloader needs to remap the exception vector table because the exception vectors are still pointing to the exception handler in the boot ROM when the preloader starts executing. By setting the L3 interconnect remap bit 0 to high, the on-chip RAM mirrors to the lowest region of the memory map. After this remap, the exception vectors will use the exception handlers in the preloader image.

The figure below shows the memory map before and after remap.

Figure A-12: Remapping the On-Chip RAM



The preloader can reconfigure all HPS clocks. During clock reconfiguration, the preloader asserts reset to the peripherals in the HPS affected by the clock changes.

The preloader configures HPS I/O pins through the scan manager and pin multiplexing through the system manager. The preloader initiates the freeze controller in the scan manager to freeze all the I/O pins and put them in a safe state during I/O configuration and pin multiplexing.

The SDRAM goes through full initialization for cold boot or a partial initialization for warm boot. For full initialization, the preloader configures the SDRAM PLL before releasing the SDRAM interface from reset. SDRAM calibration adjusts I/O delays and FIFO settings to compensate for any board skew or impairment in the board, FPGA portion of the device, or memory device. For partial initialization, SDRAM PLL configuration and SDRAM calibration is not necessary.

The preloader looks for a valid next stage boot image in the next stage boot device by checking the boot image validation data and checksum in the mirror image. Once validated, the preloader copies the next stage boot image from the next stage boot device to the SDRAM.

Before software passes control to the next stage boot software, the preloader can write a valid value (0x49535756) to be read by the preloader in the `initswstate` register under the `romcodegrp` group in the system manager. This value indicates that there is a valid boot image in the on-chip RAM. The `initswlastld` register holds the index of the last preloader software image loaded by the Boot ROM from the boot device. When a warm reset occurs, the Boot ROM will load the image indicated by the `initswlastld` register if the BSEL value is the same as the last boot.

HPS State on Entry to the Preloader

When the boot ROM code is ready to pass control to the preloader, the processor (CPU0) is in the following state:

- Instruction cache is enabled
- Branch predictor is enabled
- Data cache is disabled
- MMU is disabled
- Floating point unit is enabled
- NEON vector unit is enabled
- Processor is in ARM secure supervisor mode

The boot ROM code sets the ARM Cortex-A9 MPCore registers to the following values:

- r0—contains the pointer to the shared memory block, which is used to pass information from the boot ROM code to the preloader. The shared memory block is located in the top 4 KB of on-chip RAM.
- r1—contains the length of the shared memory.
- r2—unused and set to 0x0.
- r3—reserved.

All other MPCore registers are undefined.

Note: When booting CPU0 using the FPGA boot, or when booting CPU1 using any boot source, all MPCore registers, caches, the MMU, the floating point unit, and the NEON vector unit are undefined. HPS subsystems and the PLLs are undefined.

When the boot ROM code passes control to the preloader, the following conditions also exist:

- The boot ROM is still mapped to address 0x0.
- The L4 watchdog 0 timer is active and has been toggled.

The boot ROM also saves the state of the reset cause in the `stat` register of the Reset Manager and this information is available for the preloader to read.

Shared Memory

The shared memory contains information that the boot ROM code passes to the preloader. The boot ROM code passes the location of shared memory to the preloader in register `r0`, as described in the *HPS State on Entry to Preloader* section.

The shared memory holds the last value of the `stat` register in the Reset Manager Module and a version number that is passed by the boot ROM. The value of the `stat` register in shared memory is only valid if the version number passed by the boot ROM is 0x00000000. The table below shows where the `stat` register value and version number reside in the shared memory as an offset from the address stored in register `r0`.

Table A-18: Shared Memory Locations

Shared Memory Content	Address Location	Description
Version Number	`r0` + 0x0008	The `stat` register value in shared memory is only valid if the value of this shared memory location is 0x00000000.
`stat` Register	`r0` + 0x0038	This location holds the last value the boot ROM writes to the `stat` register in the Reset Manager before it is erased.

Loading the Preloader Image

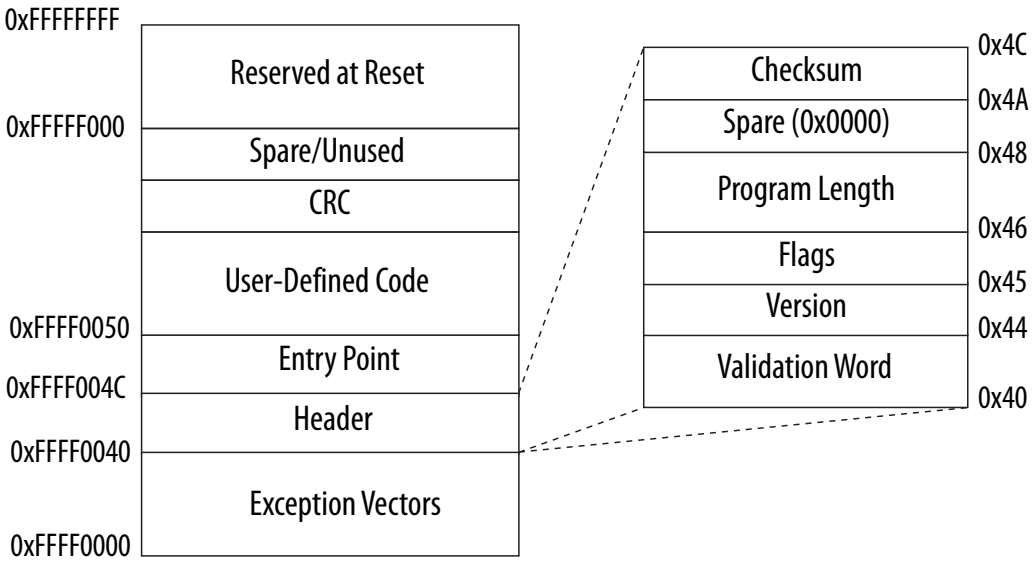
The boot ROM code loads the image from flash memory into the on-chip RAM and passes control to the preloader. The boot ROM code checks for a valid image by verifying the header and cyclic redundancy check (CRC) in the preloader image.

The boot ROM code checks the header for the following information:

- Validation word—validates the preloader image. The validation word has a fixed value of 0x31305341.
- Version—indicates the header version.
- Program length—the total length of the image (in 32-bit words) from offset 0x0 to the end of code area, including exception vectors and CRC.
- Checksum—a checksum of all the bytes in the header, from offset 0x40 to 0x49.

The preloader image has a maximum size of 60 KB. This size is limited by the on-chip RAM size of 64 KB, where 4 KB is reserved as a workspace for the boot ROM data and stack. The preloader can use this 4 KB region (for its stack and data, for example) after the boot ROM code passes control to the preloader. This 4 KB region is overwritten by the boot ROM code on a subsequent reset. The following figure shows the preloader image layout in the on-chip RAM after being loaded from the boot ROM.

Figure A-13: Preloader Image Layout



Exception vectors—Exception vectors are located at the start of the on-chip RAM. Typically, the second-stage boot loader remaps the lowest region of the memory map to the on-chip RAM (from the boot ROM) to create easier access to the exception vectors.

Header—contains information such as validation word, version, flags, program length, and checksum for the boot ROM code to validate the preloader boot loader image before passing control to the second-stage boot loader.

Entry point—After the boot ROM code validates the header, the boot ROM code jumps to this address.

User-defined code—typically contains the program code of the preloader.

CRC—contains a CRC of data from address 0xFFFF0000 to 0xFFFF0000+(Program Length*4)–0x0004. The polynomial used to validate the preloader image is:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

There is no reflection of the bits. The initial value of the remainder is 0xFFFFFFFF and the final value is XORed with 0xFFFFFFFF.

Reserved at reset—the top 4 KB is reserved for the boot ROM code after a reset. The boot ROM code uses this area for internal structures, workspace, and post-mortem dump. This area includes the shared memory where the boot ROM code passes information to the preloader.

FPGA Configuration

You can configure the FPGA portion of the SoC device with non-HPS sources or by utilizing the HPS.

When the HPS handles the initial FPGA configuration, software executing on the HPS writes the configuration image to the FPGA Manager in the HPS. Software can control the configuration process and monitor the FPGA status by accessing the control and status register (CSR) interface in the FPGA Manager.

Related Information

- **FPGA Manager** on page 4-1
  For more information regarding programming the FPGA through the HPS, refer to the *FPGA Manager* chapter.
- **Configuration, Design Security, and Remote System Upgrades in Arria V Devices**

Full Configuration

The HPS uses the FPGA manager to configure the FPGA portion of the device. The following sequence suggests one way for software to perform a full configuration:

- `CONF_DONE` = 1 and `nSTATUS` = 1 indicates successful configuration.
- `CONF_DONE` = 0 or `nSTATUS` = 0 indicates unsuccessful configuration. Complete steps 12 and 13, then go back and repeat steps 3 to 10 to reload the configuration image.
- If `DCLK` is unused, write a value of 4 to the `DCLK` count register (`dclkcnt`).
- If `DCLK` is used, write a value of 20,480 (0x5000) to the `dclkcnt` register.

If the HPS resets in the middle of a normal configuration data transfer before entering user mode, software can assume that the configuration is unsuccessful. After the HPS resets, software must repeat the steps for full configuration.

1. Set the `cdratio` and `cfgwdth` bits of the `ctrl` register in the FPGA manager registers (`fpgamgrregs`) to match the characteristics of the configuration image. These settings are dependant on the `MSEL` pins input.
2. Set the `nce` bit of the `ctrl` register to 0 to enable HPS configuration.
3. Set the `en` bit of the `ctrl` register to 1 to give the FPGA manager control of the configuration input signals.
4. Set the `nconfigpull` bit of the `ctrl` register to 1 to pull down the `nCONFIG` pin and put the FPGA portion of the device into the reset phase.
5. Poll the `mode` bit of the `stat` register and wait until the FPGA enters the reset phase.
6. Set the `nconfigpull` bit of the `ctrl` register to 0 to release the FPGA from reset.
7. Read the `mode` bit of the `stat` register and wait until the FPGA enters the configuration phase.
8. Clear the interrupt bit of nSTATUS (ns) in the `gpio interrupt` register (`fpgamgr-regs.mon.gpio_porta_eoi`).
9. Set the `axicfgen` bit of the `ctrl` register to 1 to enable sending configuration data to the FPGA.
10. Write the configuration image to the configuration data register (`data`) in the FPGA manager module configuration data registers (`fpgamgrdata`). You can also choose to use a DMA controller to transfer the configuration image from a peripheral device to the FPGA manager.
11. Use the `fpgamgrregs.mon.gpio_ext_porta` registers to monitor the `CONF_DONE` (`cd`) and `nSTATUS` (`ns`) bits.
12. Set the `axicfgen` bit of the `ctrl` register to 0 to disable configuration data on AXI slave.
13. Clear any previous DONE status by writing a 1 to the `dcntdone` bit of the DCLK status register (`dclkstat`) to clear the completed status flag.
14. Send the `DCLKs` required by the FPGA to enter the initialization phase.
15. Poll the `dcntdone` bit of the `DCLK` status register (`dclkstat`) until it changes to 1, which indicates that all the `DCLKs` have been sent.

16. Write a 1 to the dcntdone bit of the DCLK status register to clear the completed status flag.
17. Read the mode bit of the stat register to wait for the FPGA to enter user mode.
18. Set the en bit of the ctrl register to 0 to allow the external pins to drive the configuration input signals.

Partial Reconfiguration

Partial reconfiguration allows you to reconfigure part of the device while other sections remain running. The HPS performs partial reconfiguration while the FPGA portion of the device is in user mode. The following sequence suggests one way for software to perform a partial configuration:

- If PR_READY=1, continue to step 7.
- If PR_READY is 0, then go back and repeat step 5. Note that a minimum of 16 DCLK pulses are required.

If the HPS resets in the middle of a partial reconfiguration, software can assume that the configuration is unsuccessful. After an HPS warm reset, software must repeat the steps for partial configuration. After an HPS cold reset, software must repeat the steps for **Full Configuration** on page 29-34.

1. Read the mode bit of the stat register in fpgamgrregs to ensure that the FPGA is in user mode.
2. Set the cdratio bit of the ctrl register to match the characteristics of the partial reconfiguration image and set the cfgwdth bit of the ctrl register to 0 for 16-bit configuration data width.
3. Set the en bit of the ctrl register to 1 to give the FPGA manager control of the configuration input signals.
4. Set the prreq bit of the ctrl register to 1 to assert PR_REQUEST.
5. Write a value of 1 to the dclkcnt register to generate DCLK pulses for one clock cycle.
6. Poll the fpgamgrregs.mon registers to observe the PR_READY (prr) bit.
7. Write a value of 3 to the dclkcnt register to generate DCLK pulses for three clock cycles.
8. Set the axicfgen bit of the ctrl register to 1 to enable sending configuration data to the FPGA.
9. Write the partial reconfiguration image to the data register in the FPGA manager fpgamgrdata registers. You can also choose to use a DMA to transfer the configuration image from a peripheral device to the FPGA manager.
10. Poll the fpgamgrregs.mon registers to observe the PR_DONE (prd), PR_READY (prr), PR_ERROR (pre), and CRC_ERROR (crc) bits until the bits match one of the completion statuses shown in Table A–12.
11. Set the axicfgen bit of the ctrl register to 0 to disable sending configuration data to the FPGA.
12. Set the prreq bit of the ctrl register to 0 to deassert PR_REQUEST.
13. Write a value of 128 to the dclkcnt register to generate DCLK pulses for 128 clock cycles.
14. Poll the dcntdone bit of the dclkstat register until it changes to 1, which indicates that all the DCLKs have been sent.
15. Write a 1 to the dcntdone bit of the dclkstat register to clear the completed status flag.
16. Poll the fpgamgrregs.mon registers to observe the PR_DONE (prd), PR_READY (prr), PR_ERROR (pre), and CRC_ERROR (crc) bits. When all bits are set to 0, the FPGA is ready for the next transaction.
17. Set the en bit of the ctrl register to 0 to allow the external pins to drive the configuration input signals.

Document Revision History

Table A-19: Document Revision History

Date	Version	Changes
November 2015	2015.11.02	Maintenance Release
May 2015	2015.05.04	• Added "Boot Source I/O Mapping" section • Removed "*2" multiplier in CSEL3 column of the table in "CSEL Pin Settings for the SD/MMC Controller" section. • Corrected frequency values for Device frequency and controller clock in the "NAND Controller CSEL Pin Settings" table in the "CSEL Settings for the NAND Controller" section • Removed reference to Mode Reset Command in the "Quad SPI Flash Devices" • Clarified "Shared Memory Locations" in "Shared Memory" section

December 2014	2014.12.15	• Added the following sections:
		  • "Boot Overview"
		  • "FPGA Configuration Overview"
		  • "Booting and Configuration Options"
		  • "Boot Definitions" section with subsections on "Reset", "Boot ROM", "Boot Source I/O Pins", "Flash Memory Devices", "Clock Select", "I/O Configuration", "L4 Watchdog 0 Timer", "Preloader", and "U-Boot Loader".
		• Removed "Shared Memory" section

June 2014	2014.06.30	Maintenance release
February 2014	2014.02.28	Correction to "Leading the Preloader" section
December 2013	2013.12.30	• Updated figures in the Booting and Configuration Introduction section. • Updated the Rest and Boot ROM sections. • Updated the Shared Memory Block table. • Updated register names in the Full Configuration section.
November 2012	1.3	• Expanded shared memory block table. • Added CLKSEL tables. • Additional minor updates.
June 2012	1.2	Updated the HPS boot and FPGA configuration sections.

Date	Version	Changes
May 2012	1.1	• Updated the HPS boot section. • Added information about the flash devices used for HPS boot. • Added information about the FPGA configuration mode.
January 2012	1.0	Initial release.
